In the discussion which ensued in reference to the above, it was evident that the members of Council were strongly in favour of the plan, and it was agreed that steps should be taken to put it into operation with the least possible delay. It was the general feeling of the members of Council that the fee paid the doctor for such examination should in no case be less than \$4.00. It was also agreed that, as far as possible, in connection with the post-graduate work conducted by the Association, the members of the profession throughout Canada should be thoroughly informed with reference to the plan to be adopted for periodic physical examinations and it was recommended that a moving picture film be prepared to illustrate the conduction of a physical examination.

REPORT OF THE COMMITTEE ON MEDICAL EDUCATION

Mr Chairman and Members of Council —

Your Committee on Medical Education begs to report as follows —

The report of 1927 was read but in the absence of the Chairman was deferred for action until the meeting this year.

We have reviewed the ground covered by that report and finding no cause for change of views, again submit it for your consideration as follows —

In this report our aim is to deal in the main with foundation or basic principles. To go into the details of medical education, no matter how important they are in themselves, leads in most instances into the realm of the medical faculty, and the teacher. These know the various intrinsic problems better than we do, and they are, we believe, earnestly and diligently applying their large experience and good judgment to solve them.

The individual school should have, we believe, freedom of action in respect of details and methods. There must be elasticity to give adequate scope for individuality, and adaptability to the special conditions, environment and opportunity, of any or all of the Canadian medical schools and teachers. This implies—as we intend it—that any attempt to standardize should not go beyond that based on general principles. It is our opinion that the aim of the medical school should be to obtain a product, on graduation, that may be designated as a well trained, or good general practitioner. This will at least convey an idea of the standard we have in mind, in the absence of a more definite term.

To obtain this standard the curriculum must be well balanced, and so must the teaching. While daily the teacher is exerting positive efforts to that end, equally positive efforts should be made to avoid the natural tendency of students (and sometimes the teacher) to dip too far towards specialization here and there, or to utilize the findings of the laboratory as a substitute for the more arduous, but vital process of thinking, and acquiring the habit of thinking properly. We are in accord with those who urge the necessity of schools and teachers having, as the central idea, that of teaching and training the student to think properly. Thus the laboratory demonstration, the clinic, the lecture, or whatever exercise it may be, is utilized primarily to meet that requirement, and the information imparted or obtained is but a means to that end. The more this idea is applied in medical education, the fewer, we believe, will be our problems of curricula, sequence of study, time allotment, etc., and the easier their solution.

The above principle we would apply to pre medical as to medical studies.

1 —PRE-MEDICAL EDUCATION

In accord with the standard set and the principle just stated, we submit that the minimum pre medical standard should be the B.A. degree or its equivalent, or at the least two years in Arts, in which the foundation is strongly and adequately laid in the basic sciences of Physics, Chemistry and Biology. The question arises of whether they be taught as pure science entities or with some reference to their clinical application. We prefer the latter, but this is secondary to that of obtaining the correct mental training already referred to.

2 —UNDERGRADUATE MEDICAL EDUCATION

This, as already indicated, should aim at producing a well equipped general practitioner, and not a type of medical graduate who is partly specialist in one or more lines, unless possibly, in the occasional case of one taking a medical course to qualify for an institutional service, e.g., Psychiatry or Public Health. The great public demand, it would appear, is for the general practitioner trained to think properly (scientifically if you will). Thus trained and taught in correct habits of thinking he has a basis of such quality and quantity that he can pro-

REPORT OF THE COMMITTEE ON LEGISLATION

Mr Chairman and Members of Council —

The personnel of the Committee was the same as last year

In our last report we urged uniformity in medical curricula and degrees. Our meaning was misinterpreted. We did not advise standardization (a thing as undesirable as it is impossible) but rather that there should be a definite minimum requirement demanded of each teaching institution and that the qualifying degrees conferred on the completion of the minimum course should be the same throughout the Dominion. We still hold this opinion and would again urge that some attempt be made to have the universities adopt similar degrees for similar courses. Further, as the question of medical education and licensure are active topics at the meetings of the Medical Services of Canada, we suggest that our Committee be represented at their next meeting.

Our work for this year has included an attempt to pave the way for the introduction of a common final examination for both qualification and license. We sent a circular letter to the Dean of each medical faculty and also to the Registrar of each provincial college. The plan suggested was that the University and Medical Council examiners should sit together on subjects common to both examinations. Additional subjects demanded by the University could be cared for by university examiners. In this way the individuality of the University is safeguarded but the student is spared the necessity of presenting himself before two or more similar examining bodies. The role of examiners might well be dropped by the provincial colleges and their place taken by the Medical Council of Canada.

We received replies from nearly all the Deans and almost without exception the answers were favourable. We mentioned the desirability of conforming as closely as possible to the medical polity of Great Britain. Our correspondents gave us reason to believe that throughout the Dominion there is a great and sincere desire to bring about in Canada a practice similar to that obtaining in the British Isles.

At our meetings we have sought to devise a scheme which would bring the Medical Council of Canada into a position analogous to that of the General Medical Council of Great Britain. We feel that this should be done but have nothing definite to report on the subject at present.

We had one communication regarding the irregulars. This was from New Brunswick which specifically in its Medical Act accepts Osteopathy. The other provinces had nothing to report regarding them.

We have received no information regarding any charges which have been made in Medical Acts with the exception of certain projected legislation in Alberta. A bill was introduced there which would inflict upon the profession the indignity of having its members disciplined by a lay board from whose decision there is no appeal. We communicated with the local members. What action has been taken we are not able to report at this time.

We notice that other committees of the Canadian Medical Association occasionally deal with legislative matters. We would suggest that in these circumstances we be allowed to give our assistance for the same problem may have already been considered by ourselves.

During the past year our function as a committee has become much clearer to us. As we see it we have two duties—the one to endeavour to secure modification in the existing acts and the other to scrutinize legislation being considered in the various provinces. This latter function is the more important. It is indeed of supreme importance. The passing of undesirable legislation has a far reaching effect. The fact that one province has adopted a law encourages other provinces to follow suit, and so, unless we succeed in blocking the passage of one bill, we are likely to find ourselves confronted with nine acts, to modify which would be almost hopeless. Viewed

in this way our Committee becomes of supreme importance and therefore we seek its general recognition as a Committee of Safety which should be notified of, and consulted regarding all medico legal matters whether provincial or federal.

All of which is respectfully submitted

G S FAHRNI,

Chairman

Approved

REPORT OF THE COMMITTEE ON MUNICIPAL PHYSICIANS

Mr Chairman and Members of Council —

Your Committee on Municipal Physicians begs to report as follows —

Pursuing similar methods to those of last year, a communication was directed on February 7th to the different members of the Committee, which comprises medical men in each of the nine Provinces, advising that a report was desired by the Canadian Medical Association by April 15th and suggesting along what line a report might run. Four questions were asked, viz:

- (1) What is the condition of medicine as practised now?
- (2) What good points are there in it?
- (3) What is there about the present system that could and should be improved upon?
- (4) If you think it could and should be changed in some way to better the service rendered to the public and also to make it more congenial to the men in practice, what suggestions have you to offer along the lines of a change which might include partial or complete State Medicine?

Many of the members of the Committee have replied, some very briefly and offering no suggestions, while a few have gone very thoroughly into the whole subject, and have offered comment and suggestions which have been included in this report. There have been many evidences during the past few years that go to show a feeling of unrest in the minds of the people in regard to this question of health, a desire for some change which appears to have arisen out of a wish to obtain the best in the way of diagnosis and treatment, and at a cheaper cost. The question is, can any change be made without sacrificing much that is priceless both to the patient and to the practitioner as well. It is, perhaps, at first sight, easy to see and suggest new things and to discard some of the old, but will others have to go which are of vastly greater importance? At any rate it would seem necessary to decide that this question of a change is a live issue and should and must be faced, or that it is no issue at all at the present time. Our opinion is that it is a live issue and is now right on top of us, and it is up to the Canadian Medical Association to take steps to prove one of two things and to convince the public of the same—either that the present system is entirely the right one and needs only a little elaborating, or in the event of some change, that we are the ones to give it to them in the proper form.

At this juncture let us point out that it was felt to be a fact that your Committee was not in a position to set out reasons, in a convincing manner, which would satisfy the public on either the one stand or the other, but have arrived at certain conclusions which will be summed up at the end of this report. This brings us to the second part of our report, which has to do with the opinions gleaned from the members of the Committee from the different Provinces, and for the sake of convenience, we shall start at the West and move to the East.

Dr H E Ridewood, writing from Victoria, B C, has to say

"This is a very live issue just now. The British Columbia Government at its recent session has ordered an inquiry into the question of health insurance and

maternity assistance. Also the Dominion Government is considering insurance against unemployment, and also Health Insurance.

He goes on to say that the British Columbia Medical Association had adopted as a basis of possible change the report of Dr J H MacDermot. This report is included here for reference purposes, and because it expresses the consensus of opinion in the Province of British Columbia.

Also we are including in its entirety the letter from Dr H E Young, Provincial Health Officer for British Columbia, because we feel he has given a great deal of thought to the subject and his letter is valuable in that it gives reasons for the undoubted unrest and at the same time offers sound suggestions which may be helpful to any future commission dealing with the question. His letter reads as follows—

"In my opinion the criticisms that are being offered are founded on the idea that the charges for being sick are far beyond the means of the average man to pay. This idea is being fostered by those who will benefit by such criticisms of the medical profession, more especially the members of the many cults who are preying on the public.

"The medical profession receives very little credit for the amount of work that they do without the expectation of getting any pay, and also the public have no idea of the number of bills that are not paid, owing by those who are perfectly able to pay.

"If a man is ill and is sent to the hospital, on recovery he receives a bill from the physician and also one from the hospital. These, added together, make an amount which is probably much larger than any bill that this man is accustomed to receive. He immediately raises the cry of extortion.

"If this same man were to go to, say, a chiropractor, he pays for each visit and the amount is not of moment as he is accustomed to paying small bills, and it never occurs to him that, if he were to take an extended treatment and get his bill in a lump sum, it would probably be much larger than that rendered for regular services by a practitioner.

"On the other hand, those of us who are in a public position and dealing with the public, have the opportunity of knowing that present day charges are absolutely beyond their power of payment, and the doctor and hospital suffer, or the patient goes without attention unless it becomes absolutely necessary. The majority of these people are good citizens who abhor the idea of charity, and who are willing to make an effort to pay a moderate bill.

"It is this class of people that constitutes the bulk of the tax-payers and they feel that they are paying to maintain institutions from which they derive no benefit. They also feel that, if some arrangement could be made by which a stated sum or tax would be imposed upon them, they would willingly pay it in order to enable them to go to a hospital feeling that they were contributing their share for maintenance, and they were not going as charity patients.

"They pay a school tax and the children get the benefits of education, but they do not feel that they are accepting charity because they are not paying fees directly to the school, and the danger to the profession is the fact that the public may take the bit in their teeth and pass legislation providing for some measure of relief. If they do attempt this procedure, the result will be a hasty legislation which probably will not attain the object and will be a subject for acrimonious dispute for years, until finally it is adjusted to a workable basis.

"I do not think that the medical profession as a whole realize the intensity of the feeling on this subject amongst the public. The public are inarticulate but some one will come along looking for political power and will use some such scheme as a bait for votes, and I think the profession as a whole should awaken and endeavour to impress upon their respective governments that they are only too anxious to co-operate with them in an attempt to arrive at some solution of the pressing problems that are continually being presented to the governments.

"If a state tax were instituted, it should be on such a basis as would provide an amount that would give to any man or his family hospitalization, including laboratory, x-ray, and all other services for which extra charges are made. Any practitioner would have the right to write a prescription for an x-ray, laboratory services would be free, as also other departments which are considered more as an adjunct to the hospitals for which extra charges are made over and above bed fees.

"My suggestion would be that the medical fee should not be included in this. This would preserve the right of the patient to select his own physician, and what money he would have to pay out would be for his medical attendance. It would also preserve the right of the physician to accept or reject a case.

"A great change has come over hospital work in the past thirty years. We know, and the general public will admit, that medical science is a highly complex affair requiring special buildings and a highly trained staff. Anesthetics and antiseptics have made surgical treatment available for considerably more than half of all cases of serious illness. x-rays have rendered it possible to make diagnosis and prognosis certain, in many cases where formerly these were only guess work. The clinical laboratory has been evolved, and it is now no exaggeration to say that the examination and treatment of sick people is an exact scientific process, requiring the collaboration of many highly trained persons.

"Neither the public nor the profession are adjusting themselves to these advances, nor has provision been made for the financial requirements.

"A health tax would pay for all this and the result would be that the public and the profession would both benefit, the one by receiving all these services and the other, the profession, by being placed in a position where they could procure these freely and without consideration of the patient's ability to pay. The health tax would pay for this and the patient would pay for his doctor."

Letter from Dr Proctor, Vancouver, B C

"For some time, both our own profession and the general public have been realizing more and more that the present system is not productive of the greatest good either to the public or to the profession. People who have money can get all the treatment they need. The poor often go without it until too late and when they do seek it, the cost is often a tragedy for a little family and burdens them with a financial obligation from which they do not recover for years, if ever. The growing conviction of the profession in British Columbia is that some system should be devised under which every one in need of treatment should be able to get it at a fee within the means of every one, and that some modified plan of state medicine should be devised for all who possess less than a certain income—a scheme that could function for illness as the present Workmen's Compensation Board does for accidents.

"The advantages of such a scheme are obvious. A great deal of consideration has been given in this Province to the question, and following is a draft of proposals which received the endorsement of the profession of this Province through the kindness of Dr J H MacDermot, who has done a great deal of work on this question.

PRESENT MEDICAL SYSTEM

Advantages—

- "1 Choice of medical man. Every patient wants this right. It leads to wholesome competition among medical men. This is good in any kind of business.
- "2 The doctor is paid for work done—as in every other business.
- "3 Under our present system, nobody suffers as a result of poverty—the poor, in fact, have many advantages over the man of moderate income.

Disadvantages—To the doctor

"Loss of income. Many people cannot pay our fees,

many can only pay part. Much work is done free in hospitals, etc.

"Inability to do the best work in many cases on account of the expense entailed to a patient who simply cannot afford it.

"Patients do not come at the best time, namely at the onset of illness for fear of bills.

Disadvantages—To the patient

"Modern medicine if properly practised is expensive, and cannot be otherwise. Thus only the rich and the indigent can get the whole gamut of medical skill. The man of moderate income has to go without or contract bills that are a heavy burden.

"There is no room in the ordinary wage-earner's budget for more than very moderate bill. Still richer than they would be if every one paid. Those who pay, pay more because of those who do not.

"There is no provision for time loss, and the wage-earner has financial worry added to illness.

The sickness in a community is not only a burden, but affects the whole community in many ways. Infectious disease is a notable example, but all diseases in relation to environment. There is no doubt that the cost of illness over a community is considerable, and if the above principle were recognized.

Insurance against sickness is a very important and beyond the means of the working man. It is a high priority in this group.

"Undoubtedly, it is a sound principle that a proportion of the wage-earners' income should be set aside for illness and loss of time. But to do this, the charge of the group is sufficient to "charge" into the system is compulsory, is only thus. In the end, the system any such scheme be kept within bounds. The cost of payment of sickness insurance with a contribution board, (about 50%) with the other Western Canadian pension board, (about 4%).

REMEDIES SUGGESTED

"1. Panel system, as in Great Britain. This system in many ways. Too limited to provide a complete service. The cost to the patient of doctor.

"Does not provide payment for the doctor, but pays by capitation fee.

"Medical profession here is not prepared to the system for all these reasons.

"2. System of municipal health officers. This might work well in some urban and mining areas, small towns, etc.

"3. Extension of the World Health Conference Board Act principle—as at present in British Columbia. This follows the present system of medical practice more or less exactly, and is a step towards patients, as well as medical men. It is to provide a complete service, and takes prevention into account.

OTHER CONSIDERATIONS

"Preventive medicine is, as all will agree, of vital importance. This can only be done by skilled men, and otherwise there is the imputation of self-interest, and some danger of abuses. Moreover, a special training is necessary. Thus periodic medical inspection should properly be done by trained men, who would do no private practice, but would refer patients to a practicing physician for treatment.

"Any system introduced should—

- (a) Be complete. It should provide for specialist, full laboratory examinations, hospital, etc.
- (b) Follow our present system as closely as possible, to avoid dislocation and mistakes.
- (c) Be compulsory for all wage-earners within certain limits—to be determined.
- (d) Include, if possible, benefits for maternity, and for time-loss in the case of the wage-earner.

- (e) Be capable of variation to meet the diverse needs of different parts of the community.
- (f) Take into account an apportionment of the cost between patient, employer and State.
- (g) Only be adopted after the fullest consultation between all parties concerned—Labor, Medicine and the State.

"Possibly it would be wisest to do it gradually, as applied to an experimental group, as a laboratory experiment. This would minimize the danger of error, if taken.

The Alberta Member of the Committee had reported at the time this report was made out but was noted that the Government of Alberta has also an inquiry into the matter of State Medicine at its Law Commission.

(Note—Alberta goes further than British Columbia and speaks of State Medicine.)

In the Province of Saskatchewan, as was pointed out last year, we have in our R. M. Act the power given the Municipality to engage a physician on full time to grant a bonus to retain a physician in a district. There are now more than a dozen physicians in the Province under this system. A communication addressed to the members brought together from even of them. They found things working out, but as to the medical public, in general, with the all expressed their wish at the same time pointing out the perils of such a system, and some of the difficulties attached to the system of such a system, such as being too tied down and having many more calls than the remuneration. The remuneration was not adequate, though better than nothing, but it was a poor district. Most of them would prefer as before, could they finance such a system.

During the past year another step in the direction of State Medicine came in the form of a resolution of the United Labor Council, the Government of the province to give them a consultative chair. The resolution was a full and complete one. The Council who brought this combination felt that this step for free consultation would be followed by the call for free treatment. The Government got by this resolution, but the Government inquiry has been into health care in British Columbia and Alberta has been established that it will not be long before the community will have all subjects will force the government to do so.

Manitoba has not been heard from this year since the time of the making out of this report.

Dr. O'Brien—Dr. John W. S. McCulloch has answered the suggested questions in such a clear and concise manner that it has been considered best to print his "View of State Medicine" just as given, which is herewith.

"(1) What is the condition of medicine at present now?

Unsatisfactory, in some respects, both for physician and patient. The medical practitioner does too much work for which he is insufficiently remunerated, and is remunerated at all. In areas distant from medical centres there is much hardship, particularly in women and children and preventive measures are lacking.

In large centres the poor receive good service in the hospitals. The middle classes are scarcely attended and a considerable portion of the population in all communities either have no medical attention or attention is delayed when it would be most effective.

(2) What good points are there in it?

The general practitioner who, so far as the law allows, is the element in the practice of medicine has the best opportunity to render effective aid to his patient because he knows the patient's history, environment, and needs. He may, in the course of his professional life, know many, at least, two generations of people.

"For the every day ills of life the family doctor is the most valuable medical aid obtainable. Nothing is particularly in small urban and rural areas can take his place.

"But his help in prevention of disease is not utilized because outside of urban centres there is no leadership in methods of prevention such as that afforded by a whole-time, trained medical officer of health

"(3) What is there about the present system of practising medicine which could and should be improved?

"Medical aid should be made readily available to those unable to pay for it, or for whom it is not now available, by a system of state insurance, made to approximate as closely as possible to that of private practice, to which the individual of below a certain earning power, the employer and the state should contribute. In any scheme of the kind the national or provincial body of physicians should have adequate representation on the administrative body, and the physician's remuneration should be approximately that which he receives in ordinary practice so as to ensure a continuous supply of the best type of practitioner

"In the interest of the state, and of the public in any system of state medical service, the greatest emphasis should be placed upon the maintenance of health and prevention of disease. The medical officers of health should in all cases be whole-time trained men in areas of such size and financial resources as to,—

(a) Fully employ their time

(b) Foot the bill, with the assistance of both Dominion and Provincial Governments. Only in this way will that most desirable co-operation between the medical practitioner and the medical officer of health be gained

"All practitioners of medicine (the so called irregular as well as the regular) should be placed by the State on the same footing as to education and training. It is neither in the interest of the public nor of the physician to allow practise of medicine by persons of questionable qualification, who attempt to treat, for example, the communicable diseases by methods dangerous to their patients, particularly in the case of children"

From Quebec—Dr Lessard stated he had nothing to contribute

From Nova Scotia—Dr Jost gives the following very pertinent remarks

"As I see the condition, however, I can best explain it by a hunting simile. You know they say that some guns string their shot. A few go fast and far while the bulk of the load trails on so far behind that it is useless. I believe that medicine is stringing its shot. There is too great a distance between the leaders and the tailenders. The provision of hospital facilities, the trek of people in the cities, including the physicians, competition and personal ambition are placing a few in the extreme forefront while the majority trail behind, too far behind. As you know, from the point of view of the patient, each succeeding year the cry which they are making is growing in volume. They say that two classes are getting good treatment—the rich for pay, and the poor, or a few of them, for experience. The vast bulk of the people between these two extremes are becoming more and more restive each year. What I fear is that the people themselves will make the change, not the physicians"

From New Brunswick—Dr Melvin asked to be excused from acting on the Committee. However, he ventures certain statements which are included

"Your letter of February 7th, informing me that I was on your Committee, was a surprise and I think must be an error. For some years past I have not been even a member of the Canadian Medical Association, nor is it at all probable that I shall resume my membership

"However, I beg with great respect to congratulate your Association upon the courage (I will not say hardihood) displayed by it in its laudable attempt to reform this four-thousand year old profession that still projects itself into the twentieth century"

From Prince Edward Island—Dr Jenkins stated he was sure the Province of Prince Edward Island would acquiesce in any suggestions and improve the larger body

Dr Neville E Challenger, Pathologist to the Regina General Hospital, has contributed a very fine exposition of the Panel System of Great Britain, which so thoroughly explains its workings and gives in so much detail attendant evils of it that it has been forwarded as an appendix to this report, so that it may be in the hands of the Executive as a useful collection of first-hand information, gleaned while in contact with the system in England. A perusal of Dr Challenger's paper will go to show that the possibilities of disintegration and degeneration in the ranks of the medical profession are very great and all effort should be put forth to prevent any such influences entering our midst

In conclusion Taking into consideration what information we have been able to glean from all sources, we have come to certain definite decisions

1 That there is unrest on the part of the public

2 That the urge for change in the application of medical science is here and more apparent in some parts of Canada than others

3 That while there have been many changes in our social structure and also many changes within the science of medicine itself during the last quarter century, there has been little or no change in the method of applying it

4 We are certain that the time has arrived when it is necessary, as has already been said, either to prove to the public that what we are now offering is best, or, in the event of deciding that this is not the case or cannot be proven to be such, then, to prove to them that the Canadian Medical Association is both willing and able to give them whatever changes are necessary to meet their requirements

We would, therefore, respectfully urge that Council consider the immediate formation of a Commission to look into the source, origin and causes underlying the present public unrest and dissatisfaction with the practice of medicine as at present applied, and that sufficient money be secured to keep this commission at work during the entire year if necessary, and, for this purpose, the assistance of the Governments, both Federal and Provincial, might with propriety be asked, for the reason that it is a subject of vast importance to the public at large, involving the interests of the people possibly more than the profession itself

All of which is respectfully submitted

D S JOHNSTONE,

Chairman

Approved

In connection with the Report on Municipal Physicians, Dr H H Murphy presented the following reference to Health Insurance in the Province of British Columbia—

"Reference was made in a recent issue of the Labour Gazette (page 1278) to a movement in British Columbia in the direction of a provincial system of health insurance. During December, the advisory board to the Farmers' Institutes of the province submitted to a convention of that organization proposals for the inauguration of a province-wide state health insurance scheme on a contributory basis, for the benefit not only of farmers, but of all workers who are not protected by the Workmen's Compensation Act. The Board suggested also the provision of medical service for people in rural districts, particularly for maternity cases and for children. The adoption of health insurance as a general state measure was advocated by Mr E S H Winn, C

of the Workmen's Compensation Board of this province, in the course of an address to the New Westminster Board of Trade in December Mr Winn stated that health insurance had already passed the test of experience in countries where it had been tried. Moreover, the proposal for a provincial system, he said, had been approved by doctors, trade unions, hospital boards, and various societies and organizations in British Columbia. Discussing the principles of health insurance, Mr Winn pointed out that the province might properly undertake to promote public health as a national asset, and expressed the opinion that such insurance should not be conducted for profit. Many large concerns in Canada, including the railways, considered it good business, he said, to conduct their own insurance schemes. A provincial scheme would be the means of spreading over the entire population the losses due to ill-health. At the present time, he stated, less than one-third of the various hospitals were able to pay for their treatment and maintenance.

After considerable discussion on the Report of the Committee on Municipal Physicians it was decided that a Sub-Committee composed of Doctors Geo S Young, G Stewart Cameron, J G FitzGerald, and H H Murphy, with power to add, be appointed to take steps to carry out the suggestions already approved by Council, as contained in the report of the Committee as far as this may be feasible.

REPORT OF THE STUDY COMMITTEE ON NURSING, OF THE CANADIAN MEDICAL ASSOCIATION AND CANADIAN NURSES' ASSOCIATION

Mr Chairman and Members of Council —

At the meeting of the Canadian Medical Association in Toronto, in June, 1927, I was appointed Chairman of the Joint Committee which was subsequently formed and named "The Study Committee on Nursing of the Canadian Medical Association and the Canadian Nurses' Association." The appointment of this Committee was the result of a conference held during the Canadian Medical Association meeting last year, of representatives from the Canadian Nurses' Association and Canadian Medical Association and members of some of the hospitals' executives of Canada. The Committee was to be composed of three representatives from the Nurses' Association, three members from the Canadian Medical Association and one—a layman representing the Hospital Boards of Trustees. The nurses appointed, as their representatives, Misses Jean Gunn, Superintendent of Nursing, Toronto General Hospital, Kathleen Russell, Director of the Department of Public Health Nursing, Toronto University, and Jean Browne, Secretary of the Junior Red Cross Society of Canada. The representatives of this Association are Dr A T Bazin, Montreal, Dr Duncan Graham, Professor of Medicine, Toronto University, and G Stewart Cameron.

To provide funds for beginning the study, the Canadian Medical Association set apart a sum not exceeding \$300 for the year's work and the Canadian Nurses' Association authorized a similar expenditure.

The Committee met early in September of last year and after organizing, discussed the various points upon which a study should be made and also the different methods by which this study might be prosecuted. A Committee, composed of the three representatives of the Canadian Nurses' Association, was appointed to draw up, in detail, a program of the proposed study to be submitted at the next meeting. This was very carefully done and was considered by the Committee at a meeting early in October. The unanimous view of the members present was that an effort should be made to consider fully the various points raised in the sub-committee's report, but that, in order to do so, an independent investigator trained along sociological lines should be secured. The appointment of such a person would require a sum of money far beyond that at the disposal of the joint committee. It was then decided that efforts should be made to secure funds sufficient to enable us to begin this study. At a meeting held in Toronto in March, we found that the various avenues through which we expected to secure money were closed to us. It was then decided that Dr Bazin should interview the Carnegie Foundation with a view to securing from them sufficient help.

Early in May, Dr Bazin had an interview in New York with Mr Keppel, President of the Carnegie Corporation. After a very careful survey of our problem, Mr Keppel stated that, our request was a very legitimate one and he was in sympathy with it, but, owing to the present exhaustion of funds available for Canada, he could not hold out any immediate prospect of help.

The Report of our Sub-committee was published in the *Journal* of the Canadian Medical Association in the December number so that we trust many of you may have familiarized yourselves with the outline.

In submitting this report to this Association, I desire to convey to you the thought that the nurses, as represented on our Committee, are extremely anxious that a very thorough study of the whole nursing problem be made and that it be made in co-operation with the Canadian Medical Association. Their sincere desire is to bring out the facts and upon the facts as they exist in Canada, plans can be made for the future development of the nursing profession for the needs of Canadian citizens.

All of which is respectfully submitted

G STEWART CAMERON,
Chairman.

Approved

REPORT OF THE COMMITTEE ON ECONOMICS

Mr Chairman and Members of Council —

During the past year no economic question of outstanding importance has arisen with the exception of Health Insurance, which is beginning to come into prominence through the agitation in British Columbia for legislation dealing with this matter.

The first note was struck by Dr H C Wrench, M L A for Hazelton, B C, who spoke in the British Columbia House during the session of 1926-27 and advocated Health Insurance. The next move was made by the City of Kamloops, which memorialized the government in favour of Health Insurance legislation and circularized all the municipalities, asking them to consider the resolution presented by Kamloops to the government. The question was brought up in the Legislature during the past session and it is stated that the government intends to appoint a committee to study the question during the year and report back at the next session of the Legislature.

Undoubtedly, public opinion in favour of Health Insurance is steadily growing in British Columbia and it would appear to be a natural sequel to Industrial Medicine.

which is now in full operation in most of the Provinces of Canada having appeared first in British Columbia. Health Insurance is being demanded more and more by a very large section of the community. It is to some extent in operation in such countries as Great Britain and Germany but we feel that the type of State Medicine that obtains in these countries would be totally inadequate in Canada. It has principles to which the medical profession of this country should never agree, inasmuch as payment of doctors is made by panels and the payment for work done is by a capitation fee. We regard both these principles as unsound and pernicious. However, no decision can be hurriedly made as the question is a tremendously big one. Any legislation must be more or less experimental at first. Strong efforts, we feel, should be made by the medical profession to ensure that they are consulted fully before any bill is prepared. We should recommend that the following points, especially, be kept in mind—

- 1 The Canadian Medical Association should take steps to keep in touch with the situation in British Columbia and to obtain expressions of opinion from other Provinces
- 2 Any committee formed should have representatives from both city and rural districts as the conditions in each locality will greatly influence the administration of any Act
- 3 An attempt should be made to keep in touch with Labour. The Trades and Labour Council of British Columbia has endorsed Health Insurance strongly and we feel that Labour should be approached by us and co-operation maintained at every step possible. The Dominion Board of Labour should be approached.

Other points will suggest themselves as time passes. During the year a sub-committee has been engaged in drawing up recommendations with regard to Marine Hospital Acts under the leadership of Dr C W Proulx of Vancouver. He has made his separate report and this need not be considered here.

All of which is respectfully submitted

J H MacDERMOT,
Chairman

Approved

It was suggested that the Committee on Economics be asked to bring in some recommendation whereby the taxation on members of the medical profession would be decreased.

REPORT OF THE POST-GRADUATE COMMITTEE

Mr Chairman and Members of Council—

It will be noted that the figures given in this report cover the details of the Association's Post-Graduate work for the year ending September 30th, 1927. The expenses were met by the second grant of the Sun Life Assurance Company of Canada. A third grant of a similar amount, from the same Company, has enabled the Association to carry on since last September with results even more gratifying than those indicated by the following tables.

A study of these tables brings out several points of interest. The cost of administering the whole fund was about 13 per cent. In Quebec, where the work is conducted by a Provincial Committee requiring a secretary, the administration cost was about 50 per cent, in all the other Provinces combined, about 7 per cent.

There was an increase of one hundred speakers and of more than two hundred addresses over the year before. The attendance at lectures and clinics mounted to a total of 19,683, being an increase of nearly 2,500 over the previous year.

Notwithstanding these substantial increases in speakers, addresses and attendance, the total annual expenditure has diminished. It will be recalled that in the preceding year, there was a deficit of \$100 which amount was paid by the Canadian Medical Association. Perhaps this led your Committee to hew too closely to the line during the year of operation now reported. At any rate, increased experience has resulted in the saving of money here and there through the better routing of speakers and in other ways. Stated statistically, the cost per lecture per doctor has dropped from \$1 74 to \$1 46.

Total Cost	\$28,831 66	\$30,100 27
Cost per Lecture per Doctor	1 46	1 74

All of which is respectfully submitted

GEORGE S YOUNG,
Chairman

In order that the post-graduate department may operate to the best advantage in all parts of the Dominion, the provincial representatives on Council were urged to advise the General Secretary as to any changes which they would recommend in connection with the carrying on of this work in their respective provinces

REPORT OF THE LISTER MEMORIAL COMMITTEE

Mr Chairman and Members of Council —

At the request of the Lister Memorial Committee the General Secretary, Dr T C Routley, when in England, invited Sir Berkeley Moynihan to present the third Listerian Oration in 1930, on the occasion of the British Medical-Canadian Medical meeting in Winnipeg. Your Committee is very pleased to report that Sir Berkeley Moynihan has accepted this invitation and will be with us on that occasion.

It will be observed from the Treasurer's report that the Lister Fund is over subscribed and the proceeds well invested.

All of which is respectfully submitted

JOHN STEWART,
Chairman

REPORT OF THE OSLER MEMORIAL COMMITTEE

Mr Chairman and Members of Council —

Soon after the last annual meeting a meeting of the Local Nucleus was held in Hamilton. It was agreed that this Local Nucleus should be slightly enlarged and that an effort should be made to complete the organization of the Provincial Units according to the instructions of the last annual meeting. In this we have been largely successful with eight provinces so organized. In the Province of Saskatchewan, the work of this Committee is still under the direction of the Executive of the Provincial Association. All of the Provincial Units have advanced the organization work of this Committee by development within their respective provinces.

The following is a list of officers of Provincial Units —

BRITISH COLUMBIA

Dr W D Keith, *Convener*, Vancouver,
Dr J T Wall, *Secretary*, Vancouver

ALBERTA

Col F H Newburn, *Convener*, Edmonton,
Dr Duncan Smith, *Secretary*, Edmonton

MANITOBA

Dr D A Stewart, *Convener*, Ninette,
Dr G A Barager, *Secretary*, Brandon

ONTARIO

Dr J H Mullin, *Convener*, Hamilton,
Dr J W Tice, *Secretary*, Hamilton

QUEBEC

Dr Campbell Howard, *Convener*, Montreal,
Dr Maude Abbott, *Secretary*, Montreal

NEW BRUNSWICK

Dr G C Van Wart, *Convener*, Fredericton,
Dr Chas MacKay, *Secretary*, Fredericton

NOVA SCOTIA

Dr W H Hattie, *Convener*, Halifax,
Dr A C Jost, *Secretary*, Halifax

PRINCE EDWARD ISLAND

Dr J A McPhee, *Convener*, Summerside,
Dr I J Yeo, *Secretary*, Charlottetown

In addition to these a few members of the profession, non-residents in Canada, have been named by the Local Nucleus as "Members Extraordinary" of this Committee and have been invited to give criticism and advice. Archibald Malloch, Joseph Pratt, Leonard G Rowntree, and Donald McEachern. At a later date it might be found advisable to enlarge this list considerably.

It has been decided not to proceed with the organization referred to in the Supplementary Report of last year until the money for the Osler Oration (Objective, \$5,000) is in hand. Tentative plans have been considered, but the time has not arrived for developing these. These plans, however, will be available for the future work of this Committee. A very attractive offer to establish a Scholarship under the auspices of the Association was presented to Committee for consideration. We believe the time has not arrived when the details of this proposal should be presented to the members. Such action should be delayed and the proposal placed in the hands of the Section on Osler Scholarships as soon as the same is organized.

After the development of the organization of the Provincial Units, those who had been previously named as corresponding members were expected to continue to act through the organization of and as members of their respective Units. Correspondence was carried on only through the officers of the Provincial Unit.

It has been agreed that the Quebec Provincial Unit should be given the responsibility of the organization for the first Oration, the year in which it should be given, and all other details.

Arrangements were completed for a Dominion wide campaign in the late Autumn to collect the necessary funds for the work of this Committee. A copy of the last Annual Report, Subscription Form, Return Envelope, together with a short covering letter, were sent out to a list of approximately seven thousand members of the Profession, in active work in Canada.

A Progress Report of our Committee was made to the Executive at its meeting in November, in Montreal, and Dr Campbell Howard was asked to present the same and any recommendations from the Quebec Unit.

The following resolutions were received and endorsed by the Executive Committee —

RESOLVED That this Committee recommend to the Executive of the Canadian Medical Association that the first Osler Oration be given in Montreal at the annual meeting of the Canadian Medical Association in the year 1929, and that Dr F J Shepherd be

asked to deliver it, and, further, that this Committee does not approve of a symposium on this occasion

RESOLVED That the Canadian Medical Association be asked to arrange a Section of History of Medicine on the program of its annual meeting, or, failing this, to provide for at least one paper treated from the historical standpoint

Following the meeting of the Executive, arrangements were completed through the Treasurer, Dr. Bazin, whereby the Treasurer's offices opened a special account known as "The Osler Memorial Fund" with the understanding that as quickly as possible these funds would be invested. The arrangements provided that the collection of funds would remain entirely in the hands of the Osler Memorial Committee, who should pay all charges, (exchange, stamps and on drafts). Net proceeds were transferred to the Treasurer in amounts exceeding \$100, leaving a small balance on hand in the local bank.

Subscription pledges for the Osler Memorial Fund now reach a total of \$3,709.02, of which \$3,325.00 has been placed in the hands of the Treasurer of the Canadian Medical Association for investment. One subscription of \$200 has been received from an anonymous contributor, who, we understand, is a member of the Association in good standing, and another subscription whereby \$5.00 a year has been turned over to the Committee in perpetuity.

The following table shows the amount of the money received in paid up subscriptions, the number of same (N.S.) in each province, and the medical population (M.P.) of these

Province	M.P.	N.S.	Amount
British Columbia	612	9	\$ 90.00
Alberta	566	11	170.00
Saskatchewan	554	18	195.00
Manitoba	529	27	265.00
Ontario	4,000	112	1,172.00
Quebec	2,400	46	985.00
New Brunswick	264	13	150.00
Nova Scotia	516	15	146.00
Prince Edward Island	65	16	125.00
Total	9,506	267	\$3,293.00

To these, of course, will be added the anonymous contribution, and other subscriptions amounting to \$120.00 from other than members of the profession in Canada.

There must surely be a large number of men interested in Osler who would like to contribute. In order to carry on the work of the Committee there should be a fund of at least \$10,000.00. The amount received over and above the money necessary for the objective of the Oration will be needed in order to supply funds for the Secretarial work in continuance of the Committee's work. The cost of Secretarial work for this Committee, and its various Units, is surely a just charge on money collected for this purpose.

Considerable correspondence has been carried on with the other Provincial Units, but as yet we have not received actual minutes of meetings held. Nevertheless, we have every reason to believe we have aroused a widespread interest, and indications of developing activity may be judged from the following —

British Columbia requested an additional supply of reports and subscription blanks, which the Committee used for a second direct appeal. Their Committee consists of the active officers of each of their district Societies.

In Alberta at the last annual meeting of the Provincial Association the following resolution was passed —

"That this Association ally itself with an establishment of the Osler Oration, and direct the Nominating Committee to suggest a slate of the Alberta Branch of the Osler Memorial Committee of the Canadian Medical Association." An energetic and enthusiastic Committee was appointed that promised to assist in any work they may be called upon to do.

From Saskatchewan we have assurance that, as the matter is in the hands of the Executive of the Provincial

Association, we can confidently anticipate their active co-operation.

From Manitoba we quote at length from the memorandum sent out throughout the Province —

"I am sure there is just one opinion among medical men in Canada about rendering homage to the name and work of Sir William Osler, about keeping his memory and example green, and, so far as we can, keeping his fine spirit still living among all the practitioners of medicine in Canada.

"A world figure in medicine, the greatest of his day, there may well be monuments of some kind in many countries. But he was a Canadian and had all his roots in Canadian soil, birth, early life, school, teachers, inspirations and training. When he left Canada he was already a man of mark, and Canada had always a large share in his life and work. He was known while yet a Canadian to many of our middle aged and older members, and to a great many of the younger men was a friend and helper overseas.

"He was essentially a stimulator of medical men. In remembering him we keep before ourselves as high an ideal of study and practice and spirit as we could find embodied in any great physician of any time or any country, from Aesculapius to the present day."

In Ontario, in addition to the work of the Local Nucleus, a special meeting of all the members of the Committee from Ontario was held, and plans laid out for the program through which it should be possible to reach members in all of the large centres.

In Quebec special arrangements have been made for second canvass by the members of their Committee. One member has undertaken to make a special appeal to the French speaking members of the profession in that province.

The New Brunswick Committee requested special letter paper with which to make further appeal throughout their province and this has been placed at their disposal. We believe this campaign is well under way.

In Nova Scotia all the local medical societies have appointed representatives to the Provincial Unit, and also one was appointed by the Osler Club in Halifax. The Provincial Health Officer, who covers the province in his official duties, is an active member and will undoubtedly use every opportunity to assist the Committee.

From Prince Edward Island we have every assurance from the President elect, and the officers of the Unit, that the fund will meet with a generous response.

There should be no reason for discouragement at the present stage in the collection of these funds. Even now the work of the Committee is still in a preliminary stage. More intensive work must follow and it must be made possible by a further development of the organization under the direction of each Provincial Unit, so that it will reach the various Provincial Associations and the various local Medical Societies. Through these local societies it will then be possible to make a personal appeal to individual members of our profession. After the budget for the Oration has been collected from the profession in Canada as stipulated in last year's report, there should be no objection to making an appeal to the various provincial Councils, and other sources outside our own ranks.

It should not be a difficult matter to reach the required amount, providing we receive the complete co-operation of the officers and members of our Committee and its various Units, those who have already subscribed and a much larger list of the members of the profession throughout Canada who should be interested.

We not only need their financial assistance, but we should develop, what is much more important, a real interest in the life of Osler, his work, and the various phases of medical work in which he was interested.

We, therefore, recommend that this Committee be continued and instructed to develop the organization to these ends.

All of which is respectfully submitted

J. HEURNER MULLIN,

Chairman

Approved

Later, the Executive Committee, in considering certain correspondence received from the Chairman of the Osler Memorial Committee passed the following resolutions —

1 That 2,000 reprints of the Osler Memorial Committee Report be sent the Chairman of the Committee for distribution

2 That the Chairman of the Osler Memorial Committee be advised that he has power to conduct the work of his Committee as he sees fit, and that any expenses incurred in so doing will be a charge upon the funds collected, also that no expense shall be incurred for work other than that directly involved in bringing the fund up to the required amount of \$5,000

REPORT OF THE CONFERENCE ON THE MEDICAL SERVICES IN CANADA

Mr Chairman and Members of Council —

Our report, dated May 7th, 1927, on the second conference on the medical services in Canada, held in the House of Commons, Ottawa, in March 1927, was duly presented and adopted at the annual meeting of the Council of the Canadian Medical Association held in Toronto in June 1927. The very great success which was attained by that meeting of representatives from all the provinces of Canada was duly stressed in the report. Much was accomplished in correlating the various activities in the medical service in Canada and in creating a determined effort to improve, by continued effort, the efficiency of the service rendered by the medical profession throughout our country.

The whole hearted support rendered the Conference by Dr J H King, the Honourable Minister of Health for Canada, and his colleagues in the Federal Department of Health, is a matter of distinct gratification to our Association. Our sincere thanks are also due Dr King for having arranged for the publication of the full proceedings of the Conference in booklet form, 3,500 copies having been distributed to the members of our Association throughout Canada.

It may be noted that the first conference at Ottawa, which was also an unqualified success, met in December 1924. There was an interval of two years and three months between the first and the second conferences.

Having in view the value of these conferences, which has been so effectively demonstrated, it would be well for the Council of the Canadian Medical Association to consider the advisability of organizing a third conference, and making provision for it at a future date.

All of which is respectfully submitted

A PRIMROSE,
Chairman

Approved

It was reported that exception was taken by another organization to the use of the term "Medical Services in Canada" in connection with this Conference, on the ground that this nomenclature had been adopted by them some years ago. No action was taken in the matter.

REPORT OF THE COMMITTEE ON MEDICAL SURVEY OF CANADA

Mr Chairman and Members of Council —

Your Committee on Medical Survey of Canada begs to report as follows —

RATIO OF PHYSICIANS TO POPULATION

The number of doctors in Canada in the year 1924 was 1,100 less than in 1921, according to the report of the Federal Department of Health. This decrease was caused in part by (1) removal to foreign countries (where distant pastures look green), (2) deaths among the profession, (3) retirement from practice because of physical disabilities or other causes. The total from these three causes was lessened by the number of graduates who located in Canada during this period. Unfortunately, your Committee is unable to give any information regarding the relative importance of the above factors.

In 1921, the medical population numbered 8,706 and the civilian population, 8,775,853, or one physician to approximately 1,000 people. In 1924, there were 7,606 qualified practitioners, and an estimated population of nine and a half millions or one physician to approximately 1,250 people. In the United States, the ratio was 1 to 753 (1925), in Great Britain 1 to 1,089 (1921), in Switzerland 1 to 1,300 (1925), in Germany 1 to 1,942 (1912) and in France 1 to 2,833 (1912).

The following statistics are submitted for your information —

Provinces	Population (Census of 1921)	Number of Doctors (Census of Occupations 1921)	Number of Doctors (Report of Federal Dept of Health 1924)
Prince Edward Is	88,615	68	67
Nova Scotia	523,837	457	381
New Brunswick	387,876	268	256
Quebec	2,361,199	2,216	1,896
Ontario	2,933,662	3,459	3,046
Manitoba	610,118	557	260
Saskatchewan	757,510	524	560
Alberta	588,454	548	605
British Columbia	524,582	609	535
Total for Nine Provinces	8,775,853	8,706	7,606

UNEQUAL DISTRIBUTION OF DOCTORS

When a country doctor is removed by death, his place is seldom taken by another practitioner and thus the family doctor is gradually disappearing—much to the disadvantage of the public. The recent graduate prefers to locate in the city and many reasons are given in explanation—the strenuous life of a country practice, the low fees, the desire for social life and educational advantages for the children, and the lack of modern hospital facilities. Some blame the medical curriculum, stating that too much emphasis is placed on the specialties and on research and not enough on the training of general practitioners which should be the main function of a medical school. The recent graduate fails at times to realize that he can practise scientific medicine in a rural community, and his special field, as pointed out by Sir James Mackenzie, is a study of the early symptoms of disease—the life history of diabetes ten years before coma develops, or of phthisis months and years before a cavity is manifest.

On the other hand, because of increased facilities for travel and communication—improved roads, automobiles, telephone, etc—there is less need for the country doctor in certain localities.

CANADIAN MEDICINE OF THE FUTURE

Before one could predict the medical requirements of Canada in the next ten or twenty years—and now is the time to prepare, because doctors cannot be turned out according to factory specifications—one should have information regarding such items as —

- (1) The estimated civilian population
- (2) The average age of the men now in practice and their expectancy of life

(3) The average number of deaths per annum

(4) The number of medical students and the number of licentiatees

The average age of rural physicians in the United States, according to Pusey, was 52 in 1926, and their life expectancy was 19.4 years. In less than two decades practically all these men will have died and their places should be filled by recent graduates. (Pusey also stated that "country doctors can handle from 80 to 90 per cent of his cases," and that "there is too much worship of research.")

The following table indicates the number of medical students and graduates for the past six years

	<i>Students</i>	<i>Graduates</i>
1927	2,639	410
1926	2,556	517
1925	2,535	473
1924	2,672	629
1923	3,061	493
1922	3,229	434
Average	2,770	493

There has been a slight increase in the number of medical students during the past three years, although there has been a considerable decrease from the post war years.

Your Committee has sent to the members of the graduating classes of all of the Canadian universities, a complimentary copy of the Code of Ethics of the Canadian Medical Association with the hope that there may be established a more intimate relationship between the Canadian Medical Association and the younger members of the profession. Your Committee wishes to express its appreciation of the co-operation of the Deans of the Medical Schools who very kindly furnished the names and addresses of their students.

Your Committee begs to submit the following recommendations—

(1) That information be made available regarding the average age of Canadian physicians and the distribution of doctors in rural and urban communities.

(2) That efforts be continued to maintain contact between the Canadian Medical Association and the under graduates of the Canadian universities.

(3) That more details be secured concerning the undergraduates and their subsequent professional life.

All of which is respectfully submitted.

J. W. CRANE,
Chairman

Approved

In the discussion on this report it was suggested that the Association appoint a historian, whose duty it would be to compile all available details in connection with the Canadian Medical Association from the time of its organization. It was finally decided that this duty should be passed to the Committee on Personal Archives for attention.

A suggestion was also made that a student representative from each University be invited to sit in with Council at the Annual meetings, but it was decided by the Executive Committee that no action should be taken in this connection at the present time. The Executive Committee recommended that the General Secretary make use of every available opportunity of addressing the final year students in the medical faculties of the different universities.

REPORT OF THE COMMITTEE ON COLLEGE OF PHYSICIANS AND SUR- GEONS OF CANADA

Mr. Chairman and Members of Council—

Your Committee desires to report that, acting upon instructions received from the Association at the time of our last annual meeting and supplementary instructions from the Executive Committee, we have proceeded as follows—

1 We engaged the Association's solicitor to advise us on the preparation and presentation of a Bill to be introduced in the House of Commons, Ottawa, looking to the formation of the proposed College or Colleges, under Federal charter.

2 The Charter Fellows convened a meeting in the House of Commons, Ottawa, on February 23rd, 1928, when they had the privilege of discussing with the majority of the Doctor Members of the House of Commons, the proposed Bill. The discussion at that meeting showed that the members present were unanimously in favour of the establishment of the College, and pledged their hearty support to the Bill when presented in the House. The discussion was crystallized by the adoption of the following resolution—

That the whole matter be referred to all interested parties in the several provinces in order that, when the Bill is brought to the House of Commons, an intelligent and sympathetic reception will be given it by all the members of the House, who have been assured by those best qualified to advise them in their constituencies that the measure is worthy of whole hearted support.

3 The subject matter agreed upon to be incorporated in the Bill, together with the necessary preamble follows—

In view of the growth and development of medicine and its various branches, it is felt by the profession in Canada that a doctor essaying to do "special work" should have the opportunity of obtaining some distinguishing designation whereby the public may know that he has taken the various advanced studies that will qualify such for this work.

The Canadian Medical Association is fully aware that matters of education are entirely in the hands of the Provinces. The proposed College is merely a "diploma" conferring college and seems to be in the best interests of the people of Canada at large.

It would seem therefore, that there can be no reasonable ground for objection to the formation of the proposed College, which will in no way compete with nor interfere with the established educational institutions of the Dominion. The Canadian Medical Association, therefore, prays the Parliament of Canada to create such a College.

1 The College shall be entitled "The College of Physicians and Surgeons of Canada."

2 Those persons comprising the body of the College shall be known and designated as "Fellows of the College of Physicians," or as "Fellows of the College of Surgeons of Canada."

3 For the purpose of carrying out the process of incorporation a body of men has been appointed known as the nucleus of the "Charter of Fellows" of the College, the personnel being as follows—

Dr. F. N. G. Starr, *Chairman*, Toronto,
Dr. A. Primrose, Toronto,
Dr. L. J. Austin, Kingston,
Dr. A. T. Bazin, Montreal,
Dr. C. F. Martin, Montreal,
Dr. J. M. A. Rousseau, Quebec,
Dr. Geo. Hale, London.

The Body of Charter Fellows shall consist of Professors in General Medicine, General Surgery, Gynaecology and Obstetrics, who, at the present time, are actively engaged

in teaching in the universities of Canada. Provision shall also be made for the admission, without examination, for a period of one year from the date of incorporation, of those men who in the judgment of the Charter Fellows, are qualified.

4 Admission to the College, subsequent to the selection of the above two classes of Fellows, shall be by examination only, which examination shall be written, oral and practical, and shall be a severe test of knowledge, ability and judgment. The Fellowship thus granted by examination shall appertain to two classes —

- (a) Graduates of not less than three years' standing who shall be examined in all subjects named below
- (b) Graduates of fifteen years or more who shall be examined in the clinical branches only, by written, oral and practical examination, and who also shall submit a thesis. This privilege shall cease to be accorded on December 31st, 1942.

5 HONORARY FELLOWS may be selected from —

- (a) Outstanding members of the profession
- (b) Members of the profession resident in Canada who hold a degree of equal status to the Fellowship in Great Britain, or in France
- (c) Outstanding physicians, surgeons or scientists, resident outside of Canada, who have advanced the cause of science

6 In organizing the College and formulating By-Laws, it shall be provided —

- (a) That the business of the College shall be administered by a Committee of the Fellows who shall be elected by the Fellows of the College, and who shall be known as the Council of the College, and who shall hold office until their successors are elected
- (b) That this Committee shall be designated THE COUNCIL OF THE COLLEGE OF PHYSICIANS AND SURGEONS OF CANADA
- (c) The examination of candidates shall be arranged for and carried out under the direction of a Board of Examiners who are to be appointed by the Council, who shall hold office for not more than five years, and who may be re-appointed
- (d) Regulations shall be adopted for the formulating of such other By-Laws as may seem advisable, in addition to those provided for in this Recommendation, and also that regulations be made for the changing of any By-Laws, should circumstances render it advisable, in the best interests of the College
- (e) Regulations shall be made for the election of Members of Council and for their resignation and for filling vacancies, should such occur from any cause
- (f) The officers of the College shall be PRESIDENT, VICE-PRESIDENT, SECRETARY AND TREASURER (These two last may be combined). These officers shall be elected by the Council
- (g) The duties of these officers shall be properly set out in the By-Laws
- (h) Regulations shall be made governing the conduct of the Fellows and for dealing with any misconduct on the part of any Fellow
- (i) Regulations shall be made for acceptance of resignation of Fellows

7 (1)—In regard to admission to FELLOWSHIP by examination, no candidate shall be allowed to proceed to examination for FELLOWSHIP until he present to the Council of the College, at a time and in a manner to be set out in the By-Laws, satisfactory evidence of —

- (a) Having received a degree in MEDICINE AND SURGERY or either, from a University in Canada

In discussing Clause (a) of Section 7, a representative from the Province of Quebec recommended that the following words be added to this clause —

"And holding a Provincial or Federal License"

This was agreed to by Council

- (b) Having received a degree or registrable qualification in MEDICINE AND SURGERY, or either, from a university or licensing body, within the Empire or without the same, which has been recognized by the COUNCIL as having undergraduate courses equivalent in duration and thoroughness to those required for a degree in Medicine or Surgery, in the universities of Canada

(2)—For the FELLOWSHIP IN MEDICINE, the Candidate shall be examined in ANATOMY, including HISTOLOGY and EMBRYOLOGY, in PHYSIOLOGY, including BIOCHEMISTRY, in PHARMACOLOGY, (these may be taken as the first part of the examination), in PATHOLOGY, including BACTERIOLOGY, and in MEDICINE, including THERAPEUTICS and PREVENTIVE and FORENSIC MEDICINE. A candidate, on application, may be allowed to take his major examination in MEDICINE, or in PAEDIATRICS, in which case his diploma, if he is successful, shall indicate that he has taken this course. The practical examinations shall be arranged to demonstrate the candidate's ability in diagnosis and treatment.

(3)—For the FELLOWSHIP IN SURGERY, the candidate shall be examined in ANATOMY, including HISTOLOGY and EMBRYOLOGY, in PHYSIOLOGY including BIOCHEMISTRY, (which subjects may be taken as the first part of his examination), in PATHOLOGY, including BACTERIOLOGY, and in GENERAL SURGERY. If candidates apply, they may be permitted to have the major part of their surgical examination, (though they must have a knowledge of the principles of General Surgery), in OPHTHALMOLOGY, OTOLARYNGOLOGY, GYNÆCOLOGY, or OBSTETRICS, and in these cases, their diploma will indicate that they have qualified in this special course.

8 Provision shall be made that all the privileges and distinctions of the College shall be available to women on the same conditions and terms as to men.

9 Each candidate, before receiving his diploma, must subscribe to the following Declaration, or a similar one —

I do hereby solemnly and sincerely declare that I will maintain and defend all the rights and privileges of the College of Physicians and Surgeons of Canada, that I will not advertise or employ any unbecoming method of obtaining practice, or associate myself with any person who does so, that I will not publish any matter prejudicial to the interests of the College or derogatory to the honour of my profession. I also undertake to observe all the laws of the said College, made and to be made, under penalty of the forfeiture of my diploma, and of all rights I can legally demand as a FELLOW, and I will obey every lawful summons issued by order of the Council of the said College having no reasonable excuse to the contrary, And I make this solemn declaration by virtue of the provisions of the "Canada Evidence Act"

10 The Board of Examiners may refuse to proceed with the further examinations of any candidate who is reported to them as having failed in any of the subjects of the first part of their examinations.

11 Candidates for the FELLOWSHIP, failing to pass their examinations may not come up for examination again until the period of one year has elapsed.

12 Every APPLICANT FOR THE FELLOWSHIP must satisfy the COUNCIL as to his eligibility in every particular, prior to examination or admission.

Your Committee further desires to report that it has disseminated to the interested parties all the information embodied in this report, and hopes to obtain, in the not far distant future, expressions of opinion, which will enable us to proceed to introduce the Bill at the next session of the House of Commons, confidently anticipating its passage

All of which is respectfully submitted

F N G STARR,
Chairman

Approved

In approving the above report, Council instructed that the work of drawing up the Bill, together with such By-Laws and Constitution as will be necessary in connection with the formation of the College of Physicians and Surgeons of Canada, be proceeded with with the least possible delay

REPORT OF COMMITTEE ON ROYAL COLLEGE OF SURGEONS OF ENGLAND

Mr Chairman and Members of Council —

This Committee was constituted and its activities begun in June 1925. The object in view was to make it possible for Canadians to obtain the Fellowship of the Royal College of Surgeons by examination without incurring the expenditure of time and money involved in crossing the Atlantic for that purpose.

The Committee has met many times and there have been various conferences between the President and other members of the Council of the Royal College of Surgeons and the Chairman and other members of the Committee. These conferences have taken place in England and in Canada. In addition an extensive correspondence has been carried on between the Royal College of Surgeons and the Committee.

Finally our efforts have been concentrated on the attempt to provide for the conduct in Canada of the primary examination for the Fellowship. A "nomination committee" was appointed by the Royal College of Surgeons, with the following personnel —

Mr Ernest W Hey Groves, *Chairman*

Sir James Berry	Mr W Sampson Handley
Mr Wilfred Trotter	Mr V Warren Low
Sir H J Waring	Mr G Grey Turner
Mr A H Burgess	Mr Hugh Lett, C.B.E.

Sir Berkeley Moynihan, Bt, *President*

Sir Cuthbert S Wallace,	} <i>Vice-Presidents</i>
Mr F J Steward,	

An outline of a scheme prepared by the Committee was considered favourably by the Council of the Royal College of Surgeons and transmitted to your Committee in a communication dated 8th of July, 1927. Your Committee met in Montreal on November 14th, 1927, considered the scheme as drafted by the College, and suggested certain amendments, which were duly transmitted to the College in a communication dated November 21st, 1927. At a meeting of the Council of the Royal College of Surgeons held on the 9th of February, 1928, a revised scheme, embodying the suggestions made by the Committee in Canada, was approved. This revised scheme was considered by your Committee at a meeting held in Toronto on March 19th, 1928, and was approved by them. Finally this revised scheme was approved by the Executive Committee of the Canadian Medical Association held in Toronto on March 20th, 1928.

The outcome of all these negotiations is that the Royal College of Surgeons of England has arranged to conduct the primary examination for the Fellowship in

Toronto "at the end of July or in August 1929," providing a sufficient number of candidates apply.

The following is the revised scheme as approved and authorized by the Royal College of Surgeons of England and by the Executive Committee of the Canadian Medical Association

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Report of the Nomination Committee dated 2nd of February, 1928, and approved by the Council of the Royal College of Surgeons on the 9th of February, 1928, and by the Executive Committee of the Canadian Medical Association on the 20th of March, 1928

Revised Scheme for Primary Fellowship Examination to be held in Canada

- 1 The Canadian Medical Association to be appointed the authority in Canada representing the Royal College of Surgeons in connection with the proposed examination, and to be responsible for the arrangements to be made in Canada to enable the Examiners of the College to conduct the examination in that country
- 2 An examination to be held by the College at Toronto at the end of July or in August 1929, provided that it is notified to the Secretary of the College not later than the 1st of May, 1929, that there are such number of eligible candidates desirous of being examined as may be agreed by the College and the Canadian Medical Association as sufficient to warrant the holding of an examination in Canada
- 3 Two Examiners in Anatomy and two Examiners in Physiology, who shall be present or past members of the Board of Examiners in Anatomy and Physiology for the Fellowship, to be sent by the College from England
- 4 A Professor of Anatomy and a Professor of Physiology, or such other persons as may be nominated, to be appointed by the College from names submitted by the Canadian Medical Association to act as Assessors to the Examiners
- 5 The Examination, written and viva voce, of each candidate in each subject to be conducted by two English Examiners and one Canadian Assessor
- 6 The Canadian Medical Association to be invited to appoint suitable persons to visit and inspect the examination
- 7 The Questions for the Written Paper in Canada to be set by the Board of Examiners in Anatomy and Physiology for the Fellowship at the same time as those for the Written Paper for the June Examination in England, and to be taken to Canada by the Examiners sent from England
- 8 The Written Paper Examination to be held on the arrival of the Examiners in Canada, and the Viva Voce Examination as soon after as convenient
- 9 The result of the examination to be determined and announced by the Examiners in Canada on the completion of the examination
- 10 The dissections to be used at the examination to be prepared in the week preceding the examination in accordance with instructions sent out in advance, on a "subject" not previously used for any other purpose, by a superintendent of dissections appointed by the Council on the nomination of the Canadian Medical Association
- 11 Notice of the date and place of the Examination to be given in the *Journal of the Canadian Medical Association* and in such other way as may be thought desirable

- 12 The fee to be payable before admission to examination by each candidate to be \$100.00, or such other sum as may be arranged, and such fees to be collected by the Canadian Medical Association
- 13 The Royal College of Surgeons to advance the sum required for the purchase of First Class return fares to Canada
- 14 The Canadian Medical Association to pay, from the examination fees received, the expenses incurred in connection with the examination, including (1) hotel expenses at a rate not exceeding £3 per day for not more than seven days for each Examiner, (2) travelling expenses of the Examiners (other than ship fares), (3) capitation fee of £3 per candidate examined, i.e., 10s per candidate to each Examiner and Assessor, (4) cost of "subject" and fee to superintendent of dissections, (5) other incidental expenses
- 15 The Canadian Medical Association to submit to the College an account of the fees received and the expenses incurred in connection with the examination, and to transmit to the College the balance, if any, remaining
- 16 A candidate desirous of being examined must deliver to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., not later than May 1st, 1929, the following certificates —

- (1) Of Matriculation at a recognized University,
- (2) Of having completed the Examinations in Anatomy and Physiology for Degrees in Medicine and Surgery of a recognized University,
- (3) Of having dissected in a recognized Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a medical school

- (4) Of having attended in a recognized Medical School or Schools,
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall, individually, be engaged on the necessary experiments, manipulations, etc., but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
- (e) a course of Histology

ERNEST W. HEY GROVES,
Chairman

February 2, 1928

All of which is respectfully submitted

A. PRIMOSE,
Chairman

Approved

It was announced, supplementary to the above report, that the first professional examination for

the diploma of Fellow of the Royal College of Surgeons will be held in Toronto in July, 1929, and that announcements will appear in the *Journal* from time to time, as detailed information is available

REPORT OF THE COMMITTEE ON PHARMACY

Mr Chairman and Members of Council —

The Committee on Pharmacy has, during this year, made very little progress. No acute questions have been referred to it for consideration. In regard to the preparation of articles on therapeutics and pharmacy for the *Journal*, in accordance with the resolution passed at the last Annual Meeting of the Association, the Chairman has found great difficulty in getting members of the Committee to offer either concrete suggestions in regard to the character of the articles or persons to write the same. He has approached certain individuals but they were unable to give him that active support which would have made the work possible.

The Canadian Committee on Pharmaceutical Standards which is composed of representatives from the Canadian Medical Association's Committee on Pharmacy and the Canadian Pharmaceutical Association, has been making a thorough study of the British Pharmacopoeia and its defects, and has also considered the preparation of a Canadian Formulary. The progress of this Committee has been very satisfactory during the year. They have held one meeting in Montreal and a great many points have been settled by correspondence and by investigation in the laboratories of the various members. The action of this Committee has relieved the Committee on Pharmacy from the discussion of a great many details, and a report from the Committee will be submitted to the members of the Committee on Pharmacy, it is hoped, in the early months of next year.

All of which is respectfully submitted

V. E. HENDERSON,
Chairman

Approved

REPORT OF THE COMMITTEE ON CONSTITUTION AND BY-LAWS

Mr Chairman and Members of Council —

Your Committee desires to report that, acting upon instructions of the Association, the Constitution and By-Laws, with amendments to date, have been printed in booklet form, together with the Code of Ethics, and distributed to all members of the Association. The Committee expresses the hope that members will read this booklet, thereby acquainting themselves with our aims and objects, and also the procedure by which the Association carries on its work.

As no new item of business has been referred to the Committee during the past year, we have nothing further to report. This, in our opinion, indicates a highly satisfactory condition of affairs in an organization as active as the Canadian Medical Association.

All of which is respectfully submitted

T. GLEN HAMILTON,
Chairman

Approved

REPORT OF THE WORKMEN'S COMPENSATION COMMITTEE

Mr Chairman and Members of Council —

The Workmen's Compensation Committee beg to report on the passing by the legislature of the Province of Quebec of a completely revised act, legislation in which the Committee has taken an active interest

While the Province of Quebec was among the pioneers in workmen's compensation legislation (1909) the old act had become unsatisfactory. Settlements were effected by agreement, or by litigation, and no provision was made for hospital or medical expenses other than the cost of first aid treatment. Revision of the act has been under consideration for the past five or six years. The legislation recently passed provides for the appointment of a commission of three to administer the act, thus doing away with litigation and associated costs. The employer is required to take out insurance with a responsible company but provision is made under adequate guarantees for self-insurance.

The clauses which most concern the medical profession, namely those relating to medical care, are considered under the conditions which obtain in the Province of Quebec to be satisfactory, and remedy a long standing grievance. These clauses read in part as follows —

"Accidents which are provided for by this act shall, in addition, entitle the injured person or his representatives, as the case may be —

"To all medical, surgical, pharmaceutical and hospital charges according to a tariff approved by the Lieutenant-Governor in Council, as well as to charges of transporting the injured person to the nearest hospital. Wherever there is more than one hospital, the injured person may select one of his own choice,

"To the supplying, and normal renewing, during a period of twelve months, of prosthetic and orthopedic appliances, the use whereof is deemed necessary,

"The employer must procure for the injured person, whose mother tongue is French or English, the services of a physician, and, if required, of nurses speaking his language. Should he fail to do so, the injured person may provide them himself at the expense of the employer. The physicians, nurses and hospital establishments having had the care of the injured person may recover, from the employer, the head of the enterprise or the insurer, but, if there is no agreement to the contrary, only to the extent of the sums fixed by the tariff, the cost of their services on the decision of the Commission according to the special rules established and homologated by a judge of a court of competent jurisdiction upon a summary petition."

The tariff referred to has not yet been announced but it is hoped that it will be a fair and adequate one.

A schedule is included in the act indicating the percentage of permanent partial disability for specified injuries and this will serve as a guide for other injuries.

The Act is scheduled to come into force on the 1st day of September, 1928.

All of which is respectfully submitted

FREDERICK J. TEES,
Chairman

Approved

In the presentation of this report it was brought to the attention of Council that, in the Province of Quebec, there has been formed a Department of Preventive Medicine, to establish health service in industry, and to study possible causes of disease and the means of eliminating them. It was suggested that the Workmen's Compensation Committee be enlarged to include industrial

medicine, but, after consideration, it was decided that the problems involved in industrial hygiene more properly belong to the field of the Committee on Public Health.

REPORT OF THE DEPARTMENT OF HOSPITAL SERVICE

Mr Chairman and Members of Council —

The Department of Hospital Service, the youngest of the many activities of the Canadian Medical Association, has been organized because of the tremendous need for such work among the smaller hospitals in Canada. We have, at present, no national hospital organization to link up the various provincial hospital associations, and, in fact, in some provinces, no provincial hospital associations exist at all. A great many of our smaller institutions, especially those in smaller centres, are building without proper advice, they are purchasing equipment and supplies which may be unnecessary, of poor quality and obtained at a higher price than necessary, they are often inadequately organized and frequently cannot cope with the local situation. The need for the closer study of certain hospital problems was emphasized in the recent report of the Committee on Hospital Efficiency. Thanks to the generosity of the Sun Life Assurance Company the establishment of this Department has now become possible.

In operation but four months, we can already report considerable progress. The organization of the Department and the planning of the scope of our work has entailed considerable thought and effort. An Advisory Board is being formed, composed of representative hospital authorities from all parts of Canada. It has been considered advisable to include laymen as well as physicians on this Board. Hospital problems are being studied by visiting as many of our institutions as possible and discussing the local situation with superintendents, staffs and governors. By the end of the year, we hope to have visited the majority of the hospitals in each province.

Our chief activity will be to act in an advisory capacity on the many problems which arise in the course of hospital administration. This will be by correspondence and, where deemed advisable, by personal visit. We hope, also, to be of considerable assistance to the existing provincial hospital associations and to aid in the formation of such associations where they do not already exist.

To this end we are now building up a reference library on hospital topics. Hospital Administration has become a very highly specialized field in the past few years and we shall find such a library of inestimable value in working out the many details of the requests coming to this Department. We shall pay special attention to those contributors to hospital literature which are most applicable to Canadian institutions. Arrangements have been made with the American Medical Association, American Hospital Association, the Hospital Library and Service Bureau and the American College of Surgeons to work in close co-operation for mutual benefit and to prevent overlapping.

A number of special studies have already engaged our attention. The exodus of recent graduates to other countries and the resultant dearth of internes here has prompted us to undertake to find appointments for our students among our own hospitals. We have found many more vacancies than applicants and hope in subsequent years, by approaching the students at an earlier date, to retain a still higher number in Canada.

We are also making a study of the laws of each province with respect to responsibility for indigents, the extent of government and municipal aid, etc. We hope, also, to bring to the attention of the government many anomalies and impositions in the customs regulations which might well be corrected in the interests of the hospitals.

At present there is no complete nor trustworthy list of Canadian hospitals. We have found the greatest difficulty in completing our own list from the available data which have been culled from many sources. We are, therefore, very pleased to announce that we, in co-operation with the Federal Department of Health, hope to publish shortly, a complete and thoroughly up-to-date list of our Canadian hospitals.

From the very first announcement, a most gratifying response has been evident. A tangible proof that this work will meet a great need is the fact that already, in four months, over one hundred and fifty requests for advice or help have been received. We have reason to hope, also, that our Department can be very instrumental in developing a very close harmony and interchange of viewpoint between the medical staffs and the Boards of Governors.

All of which is respectfully submitted

G HARVEY AGNEW,

Secretary

Approved

In speaking to this report, Dr Agnew suggested that a small committee be named by the Chair to confer in reference to the work of this Department of Hospital Service, and later report to Council. The following committee was named: Doctors G H Agnew, J G FitzGerald, Harvey Smith, G S Cameron, F W Routley, A T Bazin, Duncan Graham, J G MacDougall, and H H Murphy.

At a later session of Council, this Special Committee presented the following resolution as a result of their deliberations —

"Resolved that an Advisory Committee be appointed to the Department of Hospital Service, composed of Doctors A K Haywood, Montreal, L A Lessard, Montreal, F W Routley, Toronto, G F Stephens, Winnipeg, H R Smith, Edmonton, and F C Bell, Vancouver, with power to add lay and medical advisors when, and if, they think it desirable."

This was approved by Council

REPORT OF THE MARINERS' COMMITTEE

Mr Chairman and Members of Council —

In respect to the work coming under the purview of your Mariners' Committee, the Provincial Medical Association in British Columbia took the following action:

WHEREAS the Canada Shipping Act relating to "Sick and Distressed Mariners" provides for the medical and surgical care and treatment of sick and injured Mariners, and,

WHEREAS provision is made for payment of said services out of such monies as Parliament may appropriate for such purposes,

THEREFORE BE IT RESOLVED—

- (a) That the Executive of the British Columbia Medical Association does hereby declare that it is opposed to the principle of the free treatment of mariners in our hospitals by the members of the said hospitals or other medical attendant.
- (b) That it is opposed to the principle of Hospital Contract, where such contract includes medical and surgical services,—see Form MHS 40, Department of Health, Marine Hospitals Service.

- (c) That remuneration for medical services be arranged directly with the doctor on the basis of the schedule of fees of the D S C R, or some modification thereof agreeable to the Canadian Medical Association Sick Mariners' Committee and the Departments of Health, Ottawa.
- (d) That the Department arrange for the services and payment of such specialists as may be required.
- (e) That for future appointments the Executive of the Provincial Medical Association nominate a number of physicians for such appointments and that the Department of Health should be respectfully asked to select from these nominees.

The Sub Committee in New Brunswick has the following to say regarding the suggestions emanating from the British Columbia Medical Association —

"The Committee wishes to report that we are in complete accord with these proposals up to and excepting those which deal with the nomination and appointment of medical attendants for the treatment of sailors. We feel that in New Brunswick, the choice of medical attendants should be left as at present or given to the selection of the sailor who requires treatment, or his agent.

"We are fully in accord with the principle that Hospital Committees or Boards ought not to be permitted to contract for medical service, and that any medical service rendered an injured or sick sailor should be paid for according to the fees of a definite schedule."

Other sub-committees are giving attention to these matters but have nothing definite to report at this time. All of which is respectfully submitted.

C W PROWD,

Chairman

In the discussion which ensued in reference to this report, it was evident that there was not a very clear understanding on the part of the members of Council as to the policy adopted by the Government with regard to supplying medical care for all those coming under its supervision. It was, therefore, agreed that the General Secretary should obtain definite information from the Government in this connection, and that this information, together with the report, should be referred back to the Committee for further study.

GOVERNMENT REPRESENTATIVE ON COUNCIL

As a result of the discussion on the previous report, the opinion was expressed that it would be a distinct advantage to have a representative of the Government (a medical man) on the Council of the Association, as he would be in possession of information which would be of very material assistance in many of the discussions. It was, therefore, resolved that the Constitution and By-Laws of the Association be amended to make provision for such a representative on Council. As this amendment could not be put into effect prior to the Montreal meeting in 1929, it was agreed that a Government representative should be present at this meeting by special invitation.

REPORT OF THE MEYERS MEMORIAL COMMITTEE

Mr Chairman and Members of Council

In bequeathing the sum of \$100 00 per year, for a period of twenty-five years, to the Canadian Medical Association,—the bequest to be known as the Meyers Memorial,—the late Doctor D Campbell Meyers designates the nature of the memorial in the following, as extracted from his will, and further supplemented in a letter under date February 27th, 1927

"As I desire to perpetuate the study of the prevention of insanity in certain of its types, to which my life has been largely devoted, and as I believe the treatment of this phase of nervous disease belongs to the general physician and the neurologist, I direct my Trustees to pay to the President of the Canadian Medical Association the annual sum of One Hundred Dollars for a period of twenty five years only to provide an honorarium to be known as the Meyers Memorial, to be awarded by a Committee consisting of the President, a physician and a neurologist, (the latter two to be chosen by the President,) to such member or guest of the Canadian or Provincial Medical Associations as shall write and read at the annual meeting of any of the said Associations the best thesis or dissertation on the study and treatment of those functional neuroses which, if untreated, or not treated sufficiently early might probably terminate in insanity, in the hope that the further study of those neuroses will lead to the formation of specially equipped wards in General Hospitals, devoted to their study and early treatment, and more especially in those hospitals where teaching to the medical student as well as the nurse is given, such theses to be submitted to and adjudged by the above Committee. Should no thesis of sufficient merit in the opinion of the Committee be read at the annual meeting of the Association the said grant shall not be made for that year by my Trustees. I desire that my good friend General John T Fotheringham, M D, shall be appointed the first physician and Dr George F Boyer the first neurologist on the said Committee, and that they shall continue thereon as long as they desire to act"

Further notes on the Functional Neuroses as mentioned in my Will

"As the present nomenclature of both functional nervous and mental disease is more or less transitory and may change materially in the next few years, it is impossible to classify definitely the type of disease referred to above. I desire however to refer to those Functional Neuroses in which the psychological symptoms form the essential part of the syndrome, and to that type of Neurosis which develops in late adolescent or in adult life in a patient of previous good mental and nervous history, especially such neurosis as has its etiology in emotional overstrain caused by excessive grief, worry, and allied conditions to which modern life is so conducive, and which, when the present illness is successfully overcome, will enable the patient to at once return to his normal life as a good and useful citizen, and thus avert any of those persistent mental symptoms which so frequently remain as a result of a period of insanity

I desire to exclude from this thesis the study of Mental Defectives, Paranoia and similar conditions of mental disease due to hereditary or organic states, since the treatment of these conditions, however meritorious it may be from a humanitarian point of view, will not, I believe, remove the abnormal mental state of these individuals. Hence the best interests of the State will be obtained by the restoration to their normal health of those individuals who previous to their illness were fully efficient as citizens

Dated this 7th day of February, A D 1927

(Signed) D Campbell Meyers "

Your Committee begs to report progress as follows —

The terms of the bequest have been given wide publicity through the medium of our *Journal*, and also by communications to the Provincial Medical Associations in Canada

The Provincial Secretaries have been requested to bring the terms of the bequest to the attention of the staffs of the mental hospitals in their respective Provinces

It is hoped by your Committee that members of the profession who are interested will co-operate, through the various Medical Associations in Canada, by way of contributions to the programs of their annual meetings

All of which is respectfully submitted

J T FOTHERINGHAM,
Chairman

Approved

CANADIAN SOCIAL HYGIENE COUNCIL

Dr Gordon Bates, General Secretary of the Canadian Social Hygiene Council, was granted a few minutes to place before those present the aims and objects of the Social Hygiene Council. The following is a summary of his remarks —

"In view of the fact that the aims and objects of the Canadian Social Hygiene Council have been changed since the last meeting of the Canadian Medical Association, it struck me as desirable that I should bring in a brief report as to the activities of the Council at this time

"The formal aims and objects, as adopted at the annual meeting held in Toronto on June 12th, 1928, are as follows —

"1 To undertake such measures as may be necessary to promote the public health, the control and elimination of communicable disease, and the development of health education

"2 To undertake such measures as may be necessary to prevent, reduce, or assist in the control of Venereal Diseases

"3 To promote such conditions of living, environment, and personal conduct as may best protect the family as an institution

"4 To co-operate with all government agencies and with the medical, dental, and nursing professions in order to secure these ends

"The alteration of these aims and objects was with the idea of bringing them into line with the actual work carried on by the Council

"During the last year the Council has carried on its work through branches organized in various provinces, and with the co-operation of both the organized medical profession and of the Departments of Health

"A Press Service on health matters reaches approximately 900 papers. This service is organized in such a way that there is no inter-

ference whatever with the educational work carried on through the newspapers by the Canadian Medical Association. The Council also has arranged for radio addresses weekly over twelve different stations, and has continued to use the health exhibit, the lecturer, and the moving picture as in the past.

"We are undertaking general education in connection with venereal disease control, periodic health examination, the county health unit, the prevention of diphtheria, and also in connection with many other matters in which the organized medical profession is interested and in which their co-operation is essential.

"The connecting link created by the appointment of Dr. Primrose to the Board of the Canadian Social Hygiene Council has been of great value, and the assistance of Dr. Primrose on many occasions has been highly appreciated.

"During the coming year, we shall continue to carry on educational work of the type described in the aims and objects as submitted at this time."

It was agreed that, for the ensuing year, Dr. A. Grant Fleming, of Montreal, should represent the Canadian Medical Association on the Board of the Canadian Social Hygiene Council.

SECTION OF FRENCH-SPEAKING MEMBERS

It was recommended to Council that consideration be given to the establishment of a section of French-speaking members at the annual meetings of the Association. It was agreed that, in so far as the Montreal meeting is concerned, this matter should be passed to Dr. Bazin for study and report.

MATERNAL MORTALITY

It was pointed out that the National Council of Women of Canada has appointed a Commission to investigate the whole matter of the seemingly high rate of maternal mortality in Canada. Miss H. P. Plumpton, of Toronto, President of the Canadian Red Cross Society, being the Chairman of the Commission. It was suggested that it would be advisable for the Canadian Medical Association to indicate to Miss Plumpton that it would be glad to send a representative to sit in to this Commission. It was agreed that Dr. W. B. Hendry and the Chairman of the Committee on Public Health should be asked to sit in to the Commission, representing the medical profession of Canada.

CHAIRMEN OF COMMITTEES

The following nominations were approved for Chairmen of Committees —

<i>Films</i> - - - - -	Dr. L. J. Austin, Kingston,
<i>Intra-Canadian Relations</i> -	Dr. J. S. Wright, Edmonton,
<i>Legislation</i> - - - - -	Dr. G. S. Fahmy, Winnipeg,
<i>Municipal Physicians</i> - -	Dr. D. S. Johnstone, Regina,
<i>Economics</i> - - - - -	Dr. J. H. MacDermott, Vancouver,
<i>Medical Education</i> - - -	Dr. E. S. Ryerson, Toronto,
<i>Post-Graduate</i> - - - -	Dr. Geo. S. Young, Toronto,
<i>Lister Memorial</i> - - - -	Dr. John Stewart, Halifax,
<i>Oster Memorial</i> - - - -	Dr. J. H. Mullin, Hamilton,
<i>Medical Services in Canada</i>	Dr. H. H. Murphy, Kamloops,
<i>Medical Survey of Canada</i>	Dr. J. W. Crane, London,
<i>Indian Affairs</i> - - - -	Dr. H. W. Wadge, Winnipeg,
<i>Royal College of Surgeons</i> -	Dr. A. Primrose, Toronto,
<i>Pharmacy</i> - - - - -	Dr. A. E. Henderson, Toronto,
<i>Constitution and By-Laws</i> -	Dr. T. Glen Hamilton, Winnipeg,
<i>Study Committee on Nursing of the Canadian Medical Association and Canadian Nurses' Association</i> - - - -	Dr. G. Stewart Cameron, Peterborough,
<i>Workmen's Compensation-Advisory Committee to the Department of Hospital Service</i> - - - -	Dr. F. J. Tees, Montreal,
<i>College of Physicians and Surgeons of Canada</i> -	Dr. A. K. Haywood, Montreal,
<i>Mariners Committee</i> - - -	Dr. F. N. G. Starr, Toronto,
<i>Meyers Memorial</i> - - -	Dr. C. W. Prowd, Vancouver,
	Dr. I. T. Fotheringham, Toronto,
<i>Central Program</i> - - -	Dr. Geo. S. Young, Toronto,
<i>Personal Issues</i> - - -	Dr. C. F. Wilde, Montreal,

The Public Health Committee and the Committee on Publicity and Health Education were united under the chairmanship of Dr. J. G. FitzGerald, Toronto.

SECTION OF UROLOGY

The General Secretary reported the receipt of a wire from the Canadian Urologists who were convening in Montreal, stating that they had decided to form a Section of Urology in the Canadian Medical Association. It was agreed that the Canadian Urologists should be given power to elect their own Chairman and Secretary for next year.

MEDICAL INSPECTION OF IMMIGRANTS

The following resolution was submitted for the endorsement of the Association —

"That the Canadian Medical Association approves the principle of medical examination of prospective immigrants (prior to embarkation) by Canadian physicians, in far as practicable. Further, that the action of the Department of Health, Canada, in endeavouring to introduce a method calculated ultimately to make this principle effective, is commended."

It was agreed that the Association approve the principle of this resolution and that the Department of Health be so advised

PRINCE OF WALES

CANADIAN MEDICAL ASSOCIATION PATRON

The following cablegram was sent to the Prince of Wales, Patron of the Association, on the occasion of his birthday —

"Canadian Medical Association in annual session assembled desires to extend sincere birthday greetings to your Royal Highness"

SUN LIFE ASSURANCE COMPANY OF CANADA

The Secretary was instructed to wire Mr Macaulay, President of the Sun Life Assurance Company, expressing the hearty appreciation of the Association of the valuable co-operation received in connection with our post-graduate work and the work of the Department of Hospital Service

ELECTION OF OFFICERS

The following officers were duly elected for the ensuing year —

<i>President</i> - - - - -	Dr S R Jenkins, Charlotte-town,
<i>President-Elect</i> - - - -	Dr A T Bazin, Montreal,
<i>Honorary Treasurer</i> - - -	Dr W G Reilly, Montreal,
<i>Editor</i> - - - - -	Dr A D Blackader, Montreal,
<i>Managing Editor</i> - - -	Dr A T Bazin, Montreal,
<i>Chairman of Council</i> - -	Dr A Primrose, Toronto,
<i>General Secretary</i> - - -	Dr T C Routley, Toronto,
<i>Secretary, Department of Hospital Service</i> - - -	Dr G Harvey Agnew, Toronto

Executive Committee

Dr H H Murphy, Kamloops,
 Dr G Stewart Cameron, Peterborough,
 Dr T Glen Hamilton, Winnipeg,
 Dr J G FitzGerald, Toronto,
 Dr A MacG Young, Saskatoon,
 Dr J S McEachern, Calgary,
 Dr Léon Gérin-Lajoie, Montreal,
 Dr J G MacDougall, Halifax,
 Dr Geo S Young, Toronto,
 Dr F N G Starr, Toronto

ANNUAL MEETING, 1929

It was agreed that the annual meeting in 1929 should be held in Montreal on June 17, 18, 19, 20 and 21

LIFE MEMBERS

It was unanimously agreed that the following members of the Association should be elected to Life Membership —

Mr I H Cameron, Toronto,
 Dr F J Shepherd, Montreal

AUDITORS

It was agreed that Messrs McDonald & Curry, of Montreal, and J H Dignam, of Toronto, should be appointed auditors of the Association's accounts for the ensuing year

HISTORICAL MEDICINE

There has been a strong feeling among members of the Association for some time past that definite steps should be taken by the Association to gather information on the history of medicine before much of the data is lost beyond recall, also that an effort should be made towards the formation of a permanent medical museum in connection with the Canadian Medical Association. With this end in view, a group of Canadian Medical Association members held a conference in Charlottetown, the result being the formation of a committee to be known as the Committee on Historical Medicine, with Dr J W Crane, of London, as Chairman and Dr J H Elliott, of Toronto, as Secretary. It was the expressed hope of the conference that a permanent Section of Historical Medicine would be formed in the Association at the earliest possible date. Any data or articles of historical interest which our members can pass along to this newly formed committee will be very highly appreciated.

CONCLUSION

Attention was given to a great many other details in connection with the work of the Association, which were passed to the various committees for consideration and report.

All of which, on behalf of the Council and Executive Committee of the Canadian Medical Association, is respectfully submitted

T C ROUTLEY,

General Secretary

An Address

ON

THE DECLINE OF INFECTIOUS DISEASE IN ITS RELATION TO MODERN MEDICINE*

By THEOBALD SMITH, M.D.,

*Director, Department of Animal Pathology, Rockefeller Institute,
Princeton*

INFECTIOUS disease does not play the dominant part on the medical stage that it did a generation ago. Since then much knowledge regarding disease in the individual, rather than that of the mass, has been acquired. Nevertheless, the fact remains that, although the microbic aspect of disease has lost some of its stimulating influence on research, the organisms are still with us and cast their myriad shadows over every department and specialty of medical practice.

THE ETIOLOGY OF INFECTIOUS DISEASE

Standing as we do at the end of half a century of work in scientific microbiology, we may well pause to consider the extensive spread and the depth of accurate information which stands to the credit of many workers since Pasteur, Lister, and Koch began their pioneer work. In 1876, Koch demonstrated the cycle of the anthrax bacillus from spore to spore in a drop of aqueous humour under a cover glass. In 1882, he announced the discovery and culture of the tubercle bacillus. In 1880, Pasteur began his work on chicken-cholera and anthrax vaccination. These discoveries represented the extent of our knowledge at that time regarding the

cause of infectious disease. Since then great progress has been made in our knowledge of infectious disease. I need only mention the isolation and culture of many pathogenic micro-organisms, the study of the power of resistance to disease acquired by the body and of the antibodies associated with it, the rise of chemotherapy, and the development of our knowledge of the protozoa, and the world of ultra-microscopic infectious agents. Giving birth to these concrete achievements were the concepts, theories, and hypotheses which, in part true, and in part false, animated the workers. It may be well on this occasion to recall some of these guiding theories which have survived and form the foundation on which my subject rests.

IMMUNITY

In the early days of the new era, infectious diseases were looked upon as straight contests between host and infectious agent. The micro-organisms entered, multiplied, and were checked and killed, or else the host succumbed. Now we know that in many cases a kind of equilibrium establishes itself, in which the micro-organism remains somewhere in the host, ready to multiply again when the host is off guard. In others, localizations occur in which the specific bacteria multiply and survive for a time. The victims of these conditions are now called "carriers." The concept of "the carrier" was

* The presidential address, somewhat abridged, delivered before the Congress of American Physicians and Surgeons, Washington, D.C., May 1, 1928. The complete paper appears in the September number of the *Journal of Preventive Medicine*.

developed chiefly with protozoan diseases. In the bacterial diseases it first took root when an intensive study of diphtheria developed as a result of the discoveries of toxin and antitoxin. So-called "focal" infections are types of this condition, and represent local forms of disease towards which the host is partially immunized. Bacteria, notably spores of anaerobes, may maintain themselves for a time in the system without multiplying. They may enter through fresh wounds of the skin or mucous membrane, and the liver, draining the digestive tract, often contains organisms of intestinal origin. Such bacteria may serve to explain certain rare complications following surgical operations and urinary infections in the absence of other manifest causes. The concept of "the carrier" is thus a complex one, and involves as many possibilities as there are species of micro-organisms capable of surviving in the tissues.

No one subject in the domain of pathology appears to be of so much importance as the problems connected with the defence developed and maintained by the body against foreign living matter. The importance of this has been recognized from the very beginning of the bacteriological era. The remarkable success of Jenner's cowpox, long before any organized investigation of infectious disease had been started, stimulated Pasteur to undertake his studies in fowl-cholera and anthrax. Since that time there has been no end to the procession of methods for the protective inoculation against disease. Here, as in other fields, empiricism was in advance of organized scientific enquiry, and harvested some notable triumphs of permanent value.

It was in 1884 that Metchnikoff published his first paper on phagocytosis, as observed in a disease of a small crustacean (daphnia) occurring in an aquarium. He was able to watch the spores of the microbe, as they penetrated into the body, become surrounded and engulfed by these wandering cells. This new theory of cellular defence proved highly intriguing, and stimulated further investigation. The discovery of antitoxin as a purely humoral agent of defence in 1890 added to the interest, and gave rise to a controversy regarding the relative significance of these two theories. Since then we have learned that the processes started by invading organisms in the body form a series of

highly complicated biological reactions, no one of which can be directly credited with being protective or offensive, since in every disease the cellular and humoral response must be specially analyzed and evaluated.

Phagocytic cells may take up bacteria in large numbers yet the process may prove fatal. Protozoa make a specialty of living within cells, both epithelial and wandering, during a portion of their cycle within the host. The phylogenetic significance of these groups of mobile and mobilizable cell-types was referred by Metchnikoff to ancestral processes of nutrition in very low forms. In the case of not a few of these invasive organisms the defending cells actually become a support and comfort to the enemy. At present, we are forced to acknowledge that, while we know a large number of interesting cellular and humoral actions and reactions, we have not yet learned to piece them together satisfactorily for any one disease.

Aided by studies in genetics we are beginning to understand that we cannot add to or subtract from the original dower of capacities we received from our ancestors. Medicine may assist greatly by determining the maximum capacity of these innate powers and furthering them by adequate stimuli. It cannot add to the capacity to produce protective bodies through vaccination, but it is in a position to stimulate and mobilize, by proper methods, primary latent protective energies. Fortunately, individuals of the same species do not differ among themselves to such a degree as to jeopardize current methods of mass vaccination, but it must always be borne in mind that towards any infectious disease a few individuals may be inadequately provided with protective capacity, even under maximum stimulation by vaccination procedures. It is still a question whether the immunity or susceptibility of individuals is correlated with any anatomical or physiological character. The impression acquired from experimentation is that relative susceptibility is a character by itself, and not predictable from any other bodily function.

It has been customary to speak of natural as distinguished from acquired immunity. Certain species are definitely immune to diseases to which other species succumb. This type of immunity is probably dependent on quite different factors from those possessed by resistant in-

dividuals of a susceptible race. In the latter the immunity appears to depend on the capacity of the individual to reproduce and mobilize certain protective antibodies quantitatively. In the naturally immune these are not needed. The term "acquired immunity" would appear to be misleading. Man and all susceptible animals have a certain fundamental resistance, even when the race has not been in contact with the specific micro-organism. What is really meant by the term is that the individual has simply strengthened or augmented his original resistance in the presence of specific infection.

As a corollary of the various established laws in immunology it has been generally accepted that the animal organism is a unity in its efforts to protect any tissue or organ. The effect of Jenner's local vaccine pustule must have forced this principle to the front long ago. With the development of our knowledge of immunology the fact has been accentuated over and over that any local multiplication of infectious agents spreads its influence through the entire system. A single small tubercle allergizes the whole body. Antibodies are poured into the blood so quickly that the higher local immunity produced by the inoculation can be distinguished only with great difficulty.

VARIATIONS IN THE TYPE OF ORGANISM

Second in importance to the concept of immunity is that of the variability of micro-organisms. Shortly after their discovery wild theories arose about the changes which micro-organisms may undergo. To counteract these heterodox assumptions Koch and his followers became rather too rigid adherents of the theory of the stability of pathogenic materia, and time was required before the newer idea of variability got a foothold. Slowly facts accumulated proving that no pathogenic micro-organism was without variants. The source and origin of many varieties of the same species remained obscure. It was noted however that bacteria gradually lose their virulence, or mutate into almost non-virulent types, under conditions of artificial culture. Variations among pathogenic micro-organisms are probably induced in the human and animal body by meeting in the tissues a variety of opposing conditions to which they must adapt themselves.

It would appear that the infectious diseases of

the human race probably originated in its animal ancestors, and passed on to primitive man and developed in an environment equivalent to that of human life. In the early history of man and his ancestors different infectious agents probably arose in different parts of the globe, and remained more or less confined on account of the limited capacity of man at that age for traveling long distances. Even migration and wars were slow in their progress, and diseased individuals were left behind or succumbed by the way. The discovery and use of any means of rapid transportation might have been highly destructive to the early races of mankind. It is to be remembered also that in those early days man lived in close contact with his domesticated animals. Even to-day, in the East, domestic animals are housed under living quarters.

In view of these facts, the question arises "What are the possibilities for the appearance of new or modified types of infectious disease, when micro-organisms transferred to other species change their physiological characters, and, owing to this change, become infectious for man?" Changes in the host are probably responsible for the many micro-organisms closely related to one another but not absolutely identical. Thus the three races of tubercle bacilli have probably been derived from one ancestral type. An illustration of my theme is the recent and more or less sudden sporadic appearance of undulant or Malta fever at a distance from its supposed primary centre about the Mediterranean. Instances of this infection have been reported within recent years from various places in the United States, Denmark, Germany, and Rhodesia, while the number of cases in Italy and other endemic regions appears to have increased. How are we to account for this occurrence? The organism of Malta fever in goats has been recognized since 1889, and the closely related form producing abortion in cattle since 1897. Another race has been noticed in swine since 1914. It is my belief that this porcine variety has been developed from cattle in recent times in the middle west, as a result of the close association of the animals in their feeding grounds, and the adaptation of the bovine variety to the pig under certain unknown conditions. If the bovine variety is regarded as responsible for undulant fever in man, why is it that these cases in man have appeared only

within the past three or four years, whereas according to evidence developed in my laboratory this micro-organism was active in dairy herds as far back as 1893. It is probable that everyone who has drunk raw milk has ingested this micro-organism once or many times. It would therefore appear probable that the bovine organism is only feebly capable of multiplying in the human system, but the passage of this micro-organism through the pig has made it more virulent for man, and that some of this modified porcine type has got back into the udder of cows, and thus established small centres of human disease. If nothing had been known of the animal diseases furnishing this human infection we might have been led astray in our speculation and regarded it as non-infectious, and might have failed to turn to animals as the probable reservoirs of the organism.

Taking these facts into consideration we may visualize the possibilities for new diseases to appear. The cause of the decline of the epidemic form of infectious disease has frequently been referred to the gradual rise of specific resistance in the host as a result of mild infections. It has also been claimed that there are certain more highly resistant individuals who, being spared, transmit this resistance to their offspring and so build up an immune population. Populations exposed to a strange disease suffer in epidemic form. The population furnishing the infection may not even be outwardly diseased. In general, in the great epidemics which have spread rapidly over large areas of the earth's surface their causal organisms have a special history and have come from an environment different from that into which they are lodged when they produce their wide-spread effects. In some cases, too, virulent races of micro-organisms would appear to have become extinct because the host perished before the period of excretion began. Other microbial races may have then taken their place. As a result of an interaction between the cells and fluids of the host and the micro-organism virulence has become reduced, so that finally we get a slight rise of specific resistance in the general population, and also an adaptation of the microbial cause to living conditions in the new host, which means a virulence lowered to a certain equilibrium level. After this has been reached the disease may become endemic, with

small epidemic outbursts from time to time. A gradual reduction in mortality occurs, in which economic and medical influences play a part. In this way, in my opinion, a modification of the epidemic virus takes place, and we meet with a more tractable, less destructive organism, which probably never returns to its original level of virulence. Viewed from this angle, the flora of the mucous membranes may be either the degenerated survivors of recent or ancient epidemic types, or else saprophytes adapting themselves to a parasitic state. Even the ubiquitous *B. coli* may have a history.

In discussing the factors that have led to a general decline in the mortality due to infectious disease three agencies are cited as claiming more or less of a victory: the changes in economic conditions, the application of medical science, and the interplay of natural forces, still largely unknown and not controlled by human foresight, which tend to raise the resistance of the host and reduce the virulence of the parasite.

Improvements in economic conditions provide the opportunity for a wider aseptic zone through personal cleanliness. Unfortunately, industrial changes lead to huge concentrations of the population, in which the individual zone is broken in upon. One result is a continuation and probable increase in respiratory affections. A decrease of intestinal infections has been accomplished through adequate water supply and the inspection of food. The sewage problem has been advanced but is still unsolved. So far we have only converted our water courses into open sewers, permitting occasional outbreaks of intestinal disease as a result.

In every detail of individual and communal life medical science has formulated protective devices to maintain health. Without the constant application of these medical and preventive safeguards the human race could not sustain itself. If it dropped to the level of animals in this respect its fate would be a reduction to animal density of population, or even worse, unless the race segregated itself into non-communicating groups. The number of diseases scattered over the globe is so great that free intercommunication on the animal level might bring so many to bear on the race as to make it impossible to continue its struggle against other natural injurious agencies.

An important function, which should not be

overlooked, is the isolation of the sick, to such an extent as to exterminate in many instances the infectious agent in the patient. How much is gained by this procedure it is difficult to state. Where the micro-organism represents a resistant type, as in tuberculosis, and where chronic carriers are the rule, the advantages of isolation and the destruction of the secretions carrying the virus consist in a reduction of the general level of infection and account for a large number of allergic individuals free from demonstrable lesions. This spontaneous vaccination in countries where such diseases prevail is probably a safeguard rather than a danger.

The value of medical science in all its forms is now so thoroughly established as part of our civilization that its loss would be disastrous, and would probably endanger the life of the social organization as at present constituted. Medical science and practice must go on and continue their evolution, parallel with that of human society, for we are perpetually mortgaged to maintain the barriers against our environmental enemies, until a world organization shall have recognized backward races as potential dangers, and as a consequence have brought the world population to a common hygienic and anti-parasitic level. The research laboratory must play a large part in the natural history study of disease, but it must subordinate its analytical tendencies to the broader view of the whole, and assist in the comparative study. Those of us who have followed the development of research over a considerable period of years have frequently been faced by the fact that what may be regarded as the luxury of one period becomes a necessity of the next. Coming generations will see established research stations in hitherto only partially explored territories, where living conditions will be created to make research not only possible but remunerative to medical science, and where all forms of disease will be objects of interest in view of their possible interrelations and the light that they may shed on our many still unsolved problems.

who called attention in fitting language to the many activities of Dr Smith in the field of science. Dr Forbes said —

Ladies and Gentlemen

"By a curious turn of the wheels of fate, one of the greatest medical scientists whom America has produced is to be presented to an American audience by a subject of Great Britain. This but shows the catholicity—the universality—of the Medical Sciences. The speaker of the evening, Dr Theobald Smith, the President of the Congress of American Physicians and Surgeons, is Director of the Department of Animal Pathology of the Rockefeller Institute for Medical Research, at Princeton. In 1886 Dr Smith made the first experiments in immunity. These were followed by the work of Behring, Roux and others. Dr Smith's study of Texas fever in 1889-1893 was not only a great advance in the science of protozoan disease, but it paved the way for the work on malaria by Patrick Manson, Ronald Ross, and Giassi. In 1893, he first published his studies on the bacillus of tuberculosis. In 1898 he made the first clear differentiation between the bovine and human types. He has taken an important and an active place amongst the students of tuberculosis ever since. In 1895, Dr Theobald Smith began his contributions on the production of toxins and antitoxines in diphtheria and tetanus. Whilst engaged in this research he made those fundamental observations on anaphylaxis which were then called "The Theobald Smith Reaction." For forty-five years his activities in research in the field of science have been constant and productive of much good. His contributions to the literature of the medical sciences have been many and of the greatest importance. It is not the good fortune of many men to do one really great thing, but to how few men it is given to be the discoverer not only of many truths, but to have so inspired others that, through their labours, pain, suffering, and death have been minimized, and the world has been made a safer and a better place to live in. Ladies and gentlemen, may I present Dr Theobald Smith."

On the important occasion of the delivery of this address, Dr Theobald Smith was introduced by Dr A Mackenzie Forbes, of Montreal,

THE USE OF SULPHOCYANATE OF SODA IN HIGH BLOOD PRESSURE*

BY ARTHUR G. SMITH AND R. D. RUDOLF

Toronto

THE question of high blood pressure has loomed very large in recent years in the mind of the profession and of the public, and often in the case of the latter an apprehension is aroused which frequently is quite unnecessary and may do much harm. The mere fact of a pressure being apparently too high does not mean that we should at once endeavour to lower it. It may be there for some good purpose, it may be compensatory and the *optimum* pressure for the individual. If we do succeed in reducing it in such a case the patient must be the loser. But there are certain cases where the rise, if associated with distressing symptoms, such as headache, dizziness, and even more serious ones, like passing aphasia or paresis, is serious, and here it is good treatment to try to lower it.

In every case of hyperpiesis it is well to regulate the environment, by enjoining mental and physical rest and relieving as far as possible all nervous strain, also to attend to the diet, reducing all substances which tend to raise the pressure. Beyond these measures it is only in those cases showing distressing symptoms that we should go further.

All cases of raised blood pressure fall naturally into three groups, and it is often possible, by a careful consideration of the history and by physical examination, to determine into which group a patient entirely or chiefly comes. These groups are, (1) Nervous, (2) Toxic, (3) Organic.

In a case where, in spite of careful regulation of environment and diet, the pressure remains elevated and there are symptoms, an endeavour should be made to lower the pressure. In emergencies, such as angina pectoris, one of the nitrites is usually used, often with immediate good effect, but in the more chronic cases certain drugs having a more prolonged action are often indicated, and it is with one of these, rather less known than most, that we will now deal. This is the sulphocyanate of sodium, potassium or ammonium, and it is with the first of these that we have chiefly worked.

HISTORY

The first work of interest in the use of the sulphocyanates was done by Claude Bernard¹ more than seventy years ago. He described experiments showing their toxic effects. He found the drug to be a direct muscle poison when given intravenously in large doses. It abolished muscular activity without producing any sensory changes. Six years later, Olliver and Bergeron² showed that the sulphocyanates had a toxic action when taken by the mouth as well as when given intravenously, but in the former instance much larger doses were required to produce similar effects. Dubreuil and Legros³ repeated Bernard's work, and attempted to use the sulphocyanates as an antidote in strychnine poisoning, but with little success. Kollocke⁴ showed that the cyanate was the active part of the salt in its effect upon muscle. Pauli⁴, in 1903, found that the sulphocyanate ion had a maximum inhibiting effect on the precipitation of protein in series with iodine and bromine ions. This led him to try its effect as a sedative in comparison with the biomides. He gave daily doses of one gram (gr 15) to neurasthenic, cardiac and tabetic patients. It was during this work that he discovered not only a sedative action but, what was more important, that some of the patients suffering from hyperpiesis were relieved of symptoms and showed marked reduction in blood pressure. Further contributions in regard to the toxicology and pharmacology were made by Lodholtz⁶, and Edinger and Treupel⁷. Nichols⁸, in 1926, reported a dozen cases of hypertension in which the blood pressure was well reduced under daily one-gram doses. He had used this treatment for fifteen years with constantly good results. The most recent report on sulphocyanate therapy comes from the Cornell Clinic. Under the direction of Dr. Gager⁹, 35 cases were treated for high blood pressure with the potassium salt. He reports beneficial results, though he used much smaller doses than others had done, and, as will be seen later, our experience coincides with his.

*Read before the Canadian Medical Association Meeting, Charlottetown, P. E. I., June, 1928.

CHEMISTRY

The sulphocyanates as a group include the ammonium, potassium and sodium salts. The sulphocyanate of soda, which was the substance that we used chiefly, is an alkaline, white, crystalline body, very soluble in water and alcohol. It occurs normally in body fluids and secretions, such as the tears, saliva, gastric juice and urine. It is produced by breaking down of proteins containing sulphur. It is believed to be formed in the salivary glands, excreted, swallowed and then absorbed into the system. The ordinary sulphocyanate content of the saliva is about 0.01 per cent, but this varies under different conditions, for example, it is decreased by the administration of iodine and increased by tobacco⁸.

Sulphocyanates can be detected in the saliva, tears, or urine in dilutions of 1-10,000 by the addition of a drop or two of ferric chloride solution. The resultant colour is a dark red which decolourizes on the further addition of an excess of mercuric chloride. These colour reactions do not take place if the mixture is decidedly alkaline.

PHARMACOLOGY AND TOXICOLOGY

Taken by mouth in a simple aqueous solution, daily doses of fifteen grains of sodium sulphocyanate are usually tolerated over a period of at least three weeks without any untoward result. Excretion takes place through the salivary glands, kidneys, and slightly in the stools. The saliva and urine show a marked increase in their sulphocyanate content while the drug is being taken, and this persists for several days after its discontinuance. That the drug is only slowly got rid of is also shown by the persistence of its therapeutic effects after it has been stopped.

As a result of the chemical action of the drug on the tissues, none of the sulphocyanate radicle is changed into the very toxic hydrocyanic acid. Both *in vitro* and *in vivo* the reverse change is readily effected, that is from hydrocyanic to sulphocyanic acid⁸.

The minimum lethal dose in various animals is about 500 mg per kilo of body weight. In a man of 154 lbs this would be about 30 grams, or one ounce, and in the several fatal cases on record (all of them suicidal) the amount was always much greater than this.

Lodholtz⁶ reports work of Monk, in which he showed the liver to be the storehouse of the sulphocyanates which had been given intravenously to animals. Some were also found in the spleen and the salivary glands. In the same

paper Fenwick is stated to have found that the sulphocyanates varied according to the patient's state of health. They were greatly reduced in cases of malnutrition, old age, and the wasting diseases.

The mode of action of the sulphocyanates in reducing blood pressure is as yet quite obscure, and much of the pharmacological work in this direction has been contradictory. Claude Bernard's description of the drug as a muscle poison, when given in massive doses, suggests that in therapeutic amounts it may act as a vaso-dilator. Recent work by Major respecting the increase of guanidine bases in high blood pressure is interesting when we recall that Monk showed the liver to be the storehouse of the sulphocyanates. Does the sulphocyanate bring about a fall in pressure owing to its decreasing the guanidine bases? Sulphocyanates were shown by Edinger and Trepel to increase the urinary output of sulphur and nitrogen. Pauli suggested that they acted by reducing the calcareous deposits throughout the body. He was able to demonstrate this in patients who had calcareous deposits about the teeth. The sulphocyanates may affect the blood pressure in more than one way, and further work is required before we can know the exact mode of action of the drug in this respect.

EFFECT ON NORMAL BLOOD PRESSURE

In our investigations into the action of the sulphocyanates we first studied their effects on individuals with normal blood pressures. Six persons with normal pressures were given sodium sulphocyanate in five-grain doses in water thrice daily after meals. They reacted by a fall in systolic pressure of from 15 to 30 mm in the period of one week. When the pressure fell below 100 mm the medication was stopped. They did not complain of any symptoms and were not aware of any change in their physical condition. The first patient recovered his former pressure of 130 mm in one week. The second (Case 1) continued at a lower level for nine weeks and did not regain his former pressure of 135 mm for three months.

CASE 1

A male patient, suffering from a spinal condition, confined to bed, but in good general health, was given 15 grains of sodium sulphocyanate per day for a week. His pressure had been fairly constant at 135-90 for the past two years. On the fourth day after starting the drug the pressure began to fall. On the sixth day it was 98-70 and the medication was stopped. The pressure showed a persistently lower reading (about 100 mm systolic) for two months, and it was not until the end of the third

month that it regained its former level. He complained of no symptoms and was not aware of any change in his physical condition.

A third patient continued at a much lower level for several weeks and did not regain his normal pressure of 135 mm for eight weeks. The other three all showed a considerable fall.

EFFECT ON HEIGHTENED PRESSURE

In selecting patients for treatment we did not pick any particular class, but, rather, included the general assortment of high pressure cases that ordinarily present themselves for help at a general hospital clinic. Those complicated by any acute inflammatory condition, cardiac failure, or severe kidney disease, were excluded, and only those in whom the main feature was hyperpiesis were used. In all, some seventy cases have been studied. These were divided into three groups according to the dosage employed.

Group I—In this group there were twelve cases, ten of them being bed patients. Before the medication was commenced they were kept for two full weeks in bed, to allow for any fall in blood pressure due to rest. Their pressures were taken frequently. They were then given five grains of sulphocyanate of soda thrice daily in water after food, and the blood pressures were recorded daily. Two were out-patients and their pressure readings were recorded three times a week. Eleven of the twelve showed some lowering in pressure, the length of time necessary to bring about a fall varying from thirty-six hours to one week. One patient, a case with cardio-renal damage, showed no change in pressure. The fall in the systolic pressure varied from 20 mm to 80 mm in one week. In two cases, with falls of 60 and 80 mm, there was some weakness and sense of fatigue, and in one instance there was nausea. These disagreeable symptoms lasted about six days, even after the medication was stopped. In several patients the blood pressure continued to fall for several days after administration had ceased. The most decided fall was in the systolic pressure, but in the majority of instances the diastolic was also lowered to some extent. The longest period which the pressure took to return to its former level after the drug was stopped was six weeks. Under a much reduced dosage it could be kept down.

Invariably with the reduction in pressure there was noted a diminution in tension, headache, and a disappearance of hot flushes and a lessening of nervousness. In several instances it was found

that the drug produced a sedative effect, in that the patients said that they felt drowsy. Several of them, who had previously suffered from insomnia, were now able to sleep throughout the entire night. Case 2 is a typical example of this first group, *ie*, those taking the full dose.

CASE 2

Female, aged 65, who had had hypertension for at least three years, and suffered from headache, hot flushes and weak spells. During the last year the pressure had been 260-140 or thereabouts. On February 4th, 1928, she was given sodium sulphocyanate in five grain doses thrice daily. By February 11th the pressure had fallen to 200-100 and the drug was stopped. She complained of feeling tired. On February 18th the pressure was 184-110. She was feeling much better and completely free from her persistent headache. She continued at this lower level for several weeks and when it climbed to 220 mm was put on a reduced dose of five grains of the sulphocyanate once daily, which again controlled the pressure and kept it below 200 mm.

Group II—From the observations made on the first group we decided that one gram, or fifteen grains, a day was not necessary in the majority of cases. It was also felt that the reduction of dosage might eliminate any occurrence of untoward symptoms, such as those before mentioned.

This second group included twenty patients who were attending the out-patient clinic. Their systolic pressures varied from 160 mm to 300 mm. Our aim was to bring about a moderate reduction in blood pressure, and then allow for a period of rest before again attempting to again reduce it. With this object in view we gave five grains of the drug twice daily, until the pressure showed a drop of 20 to 30 mm, then gave them three to seven days' rest before resuming the treatment. In spite of the lessened dose four of the twenty patients felt some lassitude, but only to a slight degree, and this might be accounted for as being directly due to the fall in blood pressure. It was found that the pressure could be reduced to the desired level, as with a larger dose, but the reduction was more gradual. Two of the group showed a substantial fall in the systolic pressure which was not permanent, lasting only three to five days, even when the drug was continued for some time. Ten of the twenty showed very decided improvement. They were relieved of symptoms, such as headache, dizziness, etc., and the pressures fell as much as 100 mm. They were able to carry on without sulphocyanate for periods of time varying from two weeks to two months. Case 3 is an example of this group.

CASE 3

Female, aged 46, who had suffered from headache, hot flushes and nervousness for two years. Heart normal,

no albumen in the urine, but some degree of arterio-sclerosis. The blood pressure varied between 260 and 270 mm systolic. On March 1st she was put on ten grains of sodium sulphocyanate a day. March 3rd, blood pressure 220-120, drug stopped. March 8th, blood pressure 204-120 and medication started again. March 17th, blood pressure 190-120. Drug reduced to five grains daily. A gradual fall in pressure occurred, and on March 27th this was 170-110, the patient felt better and was almost entirely relieved of her symptoms. It was found that a dose of five grains three times weekly kept her comfortable and controlled her symptoms.

While taking blood pressures a close watch was always kept on the pulse rate. Certain patients showed variations in this during treatment, but there was no evidence that this was due to the drug. The majority showed no change in the heart rate.

Group III—In this group the dose used was only five grains daily. Some forty patients were so treated, some of them being private cases, but the majority were attending the out-patient clinic. No cases complicated with nephritis were used. Four had moderately severe arterio-sclerosis, and two of these had had slight strokes some months before coming under our care. Two were diabetics, and the remainder were toxic or nervous cases of unknown origin. They were all given five grains of sodium sulphocyanate once daily in water after the evening meal. A few were tried on divided doses of $2\frac{1}{2}$ grains twice daily, with the same result. With this dose it usually required from eight days to two weeks before the systolic pressure fell to any extent. The results varied considerably but the pressure was lowered in every case in the group. In the arterio-sclerotic patients the main fall was in the systolic pressure, the diastolic remaining almost unchanged. In such patients we were unable to reduce the pressure more than thirty points, but there was a noticeable softening in the force of the beat as it came through. Two of the four in this sub-group were relieved of headaches, the others experienced no relief. The most gratifying results were obtained in the remainder of the group. The gradual fall in pressure was accompanied by relief of symptoms, such as headache, dizziness, nausea, and tension. The pressure in one case fell from 260 to 160 and in another from 240 to 150. Others showed a fall of from 200 to 140, and from 180 to 130. No disagreeable symptoms were induced. After such falls the dose was reduced to five grains every second day and in this way the excessive pressures could usually be kept in control. Cases 4 and 5 are examples of this group.

CASE 4

Female, aged 56, weighing 186 lbs. For the past year she had had headaches, hot flushes and shortness of breath on any exertion. The heart is enlarged, very little arterio-sclerosis, and no albuminuria. The blood pressure, taken on several occasions, was 190-98. On April 2nd was put on sodium sulphocyanate, five grains once a day. There was a gradual fall in pressure until April 24th, when it was 158-85. The dose was then reduced by half and continued until May 3rd when the pressure measured 138-75 and the drug was stopped. She was entirely relieved of all her symptoms and said that she "felt like a new woman." The pressure remained at the normal level for three weeks more and then commenced to climb again but was easily controlled by the drug.

CASE 5

Female, aged 46, housewife. She complained of dizziness, headache, and hot flushes for the past two months which were steadily getting worse. She was a large heavy woman, menopause more than seven years before. The blood pressure, taken on several occasions, was about 180-110. The heart was large, no murmurs heard, and no evidence of arterio-sclerosis. Urine, negative. On April 26th she was put on sodium sulphocyanate, five grains once daily. By May 5th the pressure had fallen to 140-90 and the drug was discontinued. She was greatly relieved of her symptoms and was sleeping much better. She did not require any further medication until May 29th, when a similar dose was given with similar results.

It happens that in the four high pressure cases given the patients were all females, but equally good results occurred in men.

While the number of patients treated in our series is only in the seventies, our results show that in the sulphocyanates we have a symptomatic remedy which may often be of value in a most distressing condition.

CONCLUSIONS

- 1 Sodium sulphocyanate causes a fall in the blood pressure, especially in the systolic, with usually no change in the rate of the heart.
- 2 This fall occurs when the pressure is normal as well as when it is abnormally high.
- 3 In patients showing much kidney damage or arterio-sclerosis the effect is least evident but usually occurs to some extent.
- 4 The best results are obtained in the large class coming under the heading of "essential hyperpiesis."
- 5 The sulphocyanates have been observed to have a sedative effect and are often mildly hypnotic.
- 6 They are easy to administer, and not unpleasant to take in an aromatic mixture.
- 7 A dose of $2\frac{1}{2}$ grains twice or thrice daily is sufficient to obtain the effects.

THE PREVENTION OF MATERNAL MORTALITY IN MANITOBA*

BY ROSS MITCHELL, M D,

Winnipeg

NOT a little heart burning was caused by the appearance of the report, "Maternal Mortality in Canada," compiled by Dr Helen MacMurchy, Chief of the Division of Child Welfare of the Department of Health, Ottawa, Canada. This official report, which appeared in February, 1928, showed that from July 1, 1925, to July 1, 1926, there were 1,532 maternal deaths and 237,199 births yielding a maternal mortality rate of 6.4 per 1,000 live births.

It will be observed that Manitoba has the unenviable position of having the highest rate 7.7 per 1,000 live births, followed by British Columbia, Ontario, and New Brunswick all with rates of 7 or over. So far as our province is concerned it appears to have been unfortunate in the period selected for review, as the rate, 7.7 maternal deaths per 1,000 live births, has never been reached before or since.

In Manitoba from 1921 to 1927 inclusive there have been 590 maternal deaths. The maternal death rate per 1,000 live births for Manitoba for the year 1927 is 4.8, or if three doubtful cases are included 5.0. This compares favourably with the rate of 7.7 for the period July 1, 1925 to July 1, 1926.

Let us try to think what is contained in this record of 1,532 maternal deaths in Canada in one year. Other physiological functions are performed for the benefit of the individual alone, but parturition is performed for the benefit of the race, and in performing it the mother hazards her health and even her life. How much, then, does society owe to mothers! What safeguards should be thrown about them in this high and holy duty! Yet in this age of our vaunted civilization four women in Canada per day die in

childbed. The only disease that kills off more Canadian women between the ages of fifteen and fifty is tuberculosis, and the tuberculosis death rate is diminishing, while the puerperal death rate is stationary or even increasing. Compared with European countries, Canada's position is far from satisfactory. Were the maternal mortality rate in Canada the same as in Denmark or Holland one thousand of these lives would have been saved. Compared with Great Britain, Canada has half as many maternal deaths with less than one third as many births. There is no need to stress the tremendous tragedy revealed in these figures: the loss of women in the prime of youth and beauty, the desolate homes, the motherless children. Let us consider, rather, the causes of maternal deaths and how they may be prevented.

The International List of Causes of Death, now adopted by all civilized countries, lays down eight main causes of puerperal deaths:

- 1 Accidents of pregnancy, which include abortion, ectopic gestation, moles, hyperemesis, retroversion of the gravid uterus.

- 2 Puerperal hæmorrhage, including accidental hæmorrhage, placenta prævia, post-partum hæmorrhage, adherent placenta.

- 3 Other accidents of labour, such as Cæsarean section, application of forceps, rupture of uterus, difficult labour, abnormal presentation, shock.

- 4 Puerperal septicæmia.

- 5 Puerperal phlegmasia alba dolens, embolus, sudden death.

- 6 Puerperal albuminuria, and convulsions.

- 7 Following childbirth (not otherwise defined), including puerperal insanity.

- 8 Puerperal diseases of the breast.

In the figures under review, as given by Dr MacMurchy, sepsis, or puerperal septicæmia, as in nearly all other countries, heads the list with

*Read before the North Western District Medical Society, Neepawa, February 28, 1928, and the Brandon and District Medical Association, April 30, 1928.

418 deaths, or 27 per cent of the total, hæmorrhage comes next with 357 deaths, or 23 per cent, toxæmia, including eclampsia, third with 344 deaths or 22 per cent, dystocia with 87 deaths, or 6 per cent, embolus, with 87 deaths, shock, with 63 deaths, or 4 per cent, ectopic pregnancy, with 33 deaths

It must be conceded that, even with the greatest possible care, there is a certain inevitable risk attaching to childbirth. It has been calculated that this risk is 1 per 1,000 live births. The risk will vary with the accessibility of assistance during childbirth and the character of the assistance available. Thus in a well organized, thickly settled district, with good roads and means of communication, the inevitable risk will be less than when these conditions do not obtain. To some extent this explains the discrepancy between countries such as Holland and Denmark, on the one hand, and Canada on the other. Yet we cannot lay the flattering unction of difference in physical conditions too much to our souls. The difference between these countries and ours in the maternal mortality rates is too great to be thus easily explained away.

Let us review each of the causes of death and note what steps may be taken to ward off the threatening danger. Apart from criminal abortion and sepsis, abortions and moles do not carry a high mortality. How frequent abortion is, is not known. Compulsory notification of pregnancy, which would afford a means of determining the frequency of abortions, has been proposed but it is not likely to come into force. The best treatment of abortion is judicious conservation, with operative intervention only when part of the ovum is retained.

Of the varieties of puerperal hæmorrhage, post-partum hæmorrhage claims by far the most victims. Too often post-partum hæmorrhage results from improper treatment, especially in the third stage. There is a tendency among some medical men to pride themselves on the shortness of time required to complete a maternity case. No sooner is the child delivered than the unfortunate uterus is squeezed and rubbed over the vertebral column as over a washboard, the placental cord is pulled on, and in less than five minutes the placenta is away and the doctor walks off, leaving the nurse to deal with the hæmorrhage which, unfortunately, is only occasionally excessive, but practically always occurs. In a normal labour the third stage is the most important, so far as the obstetrician is concerned.

No attempts should be made to massage the fundus except in cases of hæmorrhage, or to express the placenta until the placenta has completely separated from the uterine wall, and then expression should be attempted only during contraction of the uterus. Bleeding from the uterine sinuses is arrested by contraction and retraction of uterine muscle fibres, and exhausted muscles will not properly contract or retract. If there is any doubt as to the contractile and retractile powers of the uterus an intramuscular injection of pituitrin and aseptic ergot should be given as soon as the placenta is delivered. Accidental hæmorrhage is generally associated with toxæmia, and rise of blood pressure, or the appearance of albuminuria, should put the obstetrician on his guard. In placenta prævia the first "spotting" or small hæmorrhage is too often disregarded. No attention is paid until the case becomes one of desperate emergency. Cases of placenta prævia should be treated in the hospital, if at all possible. As soon as a definite diagnosis of this condition is made the pregnancy should be terminated.

With regard to operative measures in childbirth, there is reason to think that the adoption of Listerian principles and of anæsthesia, by making safer and less painful operations which formerly were rarely performed, has actually increased the risk in childbirth. Operative intervention is more frequently and lightly entered upon, not always because the doctor thinks there is an indication, but often in response to the pleadings of the patient and the relatives to "do something." Forceps should not be applied unless the well defined indications for their use are present. In the Winnipeg General Hospital the hypodermic needle has often replaced the forceps. A patient who has secondary uterine inertia is given 1-6 gram of morphine with 1-200 grain scopolamine. Sleep often follows and after waking the pains return and delivery is accomplished naturally. That it is possible to conduct even a teaching clinic with comparatively infrequent resort to operations is shown by the records of the public maternity ward of the Winnipeg General Hospital. In the period July 1, 1923, to Dec 31, 1927 there were 2,203 deliveries with 171 forceps operations, or 7.7 per cent, and 49 versions, or 2.2 per cent. In this period there were 7 puerperal deaths, giving a maternal mortality of 3.17 per 1,000 deliveries, about half the rate for Canada at large. Pituitrin is never used in this clinic until the second stage is completed.

We know there is a difference of opinion on this point, but we feel safer when not using this potent drug during the second stage

With regard to puerperal septicæmia there are two schools of thought, one contending that infection is always exogenous, introduced from without by hands or instruments, the other, that it is autogenous, the organisms being present in the patient's body. The truth lies probably between these extremes. Infection, no doubt, is usually introduced from without, but under certain circumstances germs within the vagina or elsewhere in the body may gain access to the uterine cavity and the blood stream. Prof R. W. Johnstone¹ of Edinburgh, in a recent address, urged his hearers to cultivate the obstetric conscience. Every labour should be conducted on sound surgical principles. If these are followed, a simple technique, even with little equipment, will produce wonderfully good results. In 1927 the Victorian Order of Nurses in Canada attended 11,016 births. Their figures indicate an average of 2.5 maternal deaths per 1,000 living births where physicians were in attendance. At a conference on puerperal morbidity and mortality, called on the initiative of the British Medical Association on January 11 last, Dr Leonard Colebrook² raised the question of the practicability of preventive immunization against the risk of puerperal infection. The hæmolytic streptococcus as the cause of puerperal fever has been known for many years, but the results of most workers along this line of inquiry have been negative. Certain experiments with vaccines have, however, been made abroad, for which encouraging results are claimed. Jotten, in Germany, starting with small doses of a vaccine found an increase in phagocytic power, and a steady decrease in the percentage of morbidity as the dose was given in larger quantities. However, it is certainly premature, at present, to suppose that the parturient woman can be successfully immunized, but the idea gives reason for serious thought.

The treatment of puerperal septicæmia is so unsatisfactory that every effort must be made to prevent it. In hospitals the investigation of every instance of post-partum elevation of temperature may reveal some focus of infection, such as a nurse or doctor with tonsillitis, sinusitis, or ozæna. In Manitoba, puerperal septicæmia is a notifiable disease, but very few of the existing cases are reported. Since October 1, 1926, in Great Britain, where notification of puerperal

septicæmia has been in force for many years, an order has been made requiring notification of all cases of puerperal pyrexia. This is defined as follows: "Any febrile condition occurring in a woman within 21 days after childbirth or miscarriage in which a temperature of 100.4°F (38°C) or more has been sustained during a period of 24 hours or has recurred during that period." The doctor is asked to state on the notification form whether he desires assistance, and, if so, whether in the form of a second opinion, bacteriological examination of blood or lochia, hospital accommodation, or trained nurse. The local authorities are urged to take steps to provide the necessary facilities.

The conditions classed under the heading "Puerperal Albuminuria and Convulsions" are responsible for many deaths. While we can never hope to be free of toxæmia, we can, with prenatal care, prevent a fatal termination in the majority of instances. The prenatal clinic at the Winnipeg General Hospital was established in January 1921, and since that time to December 31, 1927, 2,791 women have passed through the clinic. There have been many cases of toxæmia, but in no instance has a single patient who had prenatal care developed eclampsia, and, so far as I am aware, there has not been a single death from toxæmia among women who attended the clinic. Toxæmia rarely occurs as a bolt from the blue. In women who have regular routine antenatal examinations any increase in blood pressure above 140, or the occurrence of albuminuria or cedema, calls for treatment to be instituted at once. The time is coming when eclampsia will be ranked with typhoid fever as a measure of the ignorance of a community in matters of public health. Intelligent prenatal care should almost wholly prevent eclampsia. Toxæmia is particularly harmful to the fetus *in utero*, and early and adequate treatment may save not one life but two. A promising field of inquiry is opened up by a paper read before the Pennsylvania State Society on October 6th, 1927, by Harold A. Miller, M.D., and D. B. Martinez, M.D.³, of the University of Pittsburgh. In this communication they reported a series of 122 eclamptic and pre-eclamptic cases treated with "Heparphone," a liver extract. No pre-eclamptic woman developed convulsions and 14 consecutive cases of eclampsia recovered except one who had convulsions five days before treatment and was *in extremis* when first seen.

Puerperal insanity is not a frequent cause of

death, but is a source of great anxiety to all concerned. The frequent connection between post-partum hæmorrhage or sepsis, on the one hand, and the onset of puerperal insanity, on the other, deserves to be noted.

Mastitis only rarely causes death of the mother, but may contribute to the death of the child through interference with breast nursing and the consequent risk of gastro-intestinal infection, and it may also be a factor in the production of cancer of the breast in later life.

All authorities who have investigated the problem of maternal mortality have stressed the outstanding importance of pre-natal care. Sir George Newman, the Chief Medical Officer of the Ministry of Health of Great Britain, states "No sound progress can be made in the reduction of maternal mortality apart from ante-natal supervision. Such measures as inquiry into the previous obstetric history, the careful examination and control of the personal health, pelvic measurements, the estimation of disproportion between child and pelvis, and the determination of presentation, enable many risks to be foreseen and forestalled. Moreover, opportunity is thus afforded for the early recognition or treatment of concurrent conditions, such as toxæmia or venereal disease. It should become a matter of course and routine practice for every pregnant woman to place herself of her own accord, and at an early stage, under competent advice" (Maternal Mortality, 1924, H. M. Stationery Office). Dr. J. B. DeLee coined the phrase, "*Parturiens, ipso facto, est in periculo mortis*". Prenatal care offers the only way out. With prenatal care there should be also post-natal care. Dame Janet Campbell in her government report, "The Protection of Motherhood," (London, H. M. Stationery Office, 1927), says, "The value of post-natal examination is not fully recognized. Every woman ought to be examined, say, four to six weeks after confinement to make sure that everything is normal, and no maternity hospital should be satisfied finally to discharge a woman without ascertaining that no damage has been done and that no pathological condition exists which could and should be repaired. If women leaving a maternity hospital, where the labour and puerperium have been under skilled supervision, are systematically examined, a certain number will always be found in need of gynecological, or rather medical, treatment of some kind, and the proportion would unquestionably be higher among women

delivered at home. If suitable treatment is sought without delay the patient may be saved much ill-health and physical disability, and may also be spared difficulty at any future confinement."

The value of a prenatal clinic in connection with a hospital is borne out by the following figures. In the Winnipeg General Hospital during the years 1917-1920 inclusive there were 2,480 live births and 25 maternal deaths, yielding a maternal death rate of 10.09 per 1,000 live births. In January 1921, a prenatal clinic was instituted. In the period January 1, 1921, to October 31, 1927, there were 5,444 live births and 28 deaths, yielding a maternal death rate of 5.14 per 1,000 live births. In other words the maternal mortality rate was almost cut in half after the institution of organized prenatal care. A post-natal clinic was instituted in this hospital on April 28, 1926, and has been doing valuable work.

So far we have considered the problem of maternal mortality from the standpoint of the relation of the medical attendant to the patient. What may be done by the State? First, existing regulations with regard to registration of births and deaths and the notification of cases of puerperal septicæmia should be strictly enforced. Secondly, in my opinion, it would be well to have an investigation made through the Department of Health in Manitoba into every maternal death. The occurrence of the outbreaks of puerperal infection in hospitals should also be investigated. The Hospital Committee of the Welfare Supervision Board, now in session, will, no doubt, consider the advisability of locating hospitals at strategic points in districts which at present are not served by existing hospitals. In some countries, such as Great Britain and Australia, maternity benefits are paid by the State. The province of Saskatchewan provides for a payment of \$25.00 to mothers in destitute circumstances, \$10.00 going direct to the mother and \$15.00 to the doctor or hospital. In 1927, 443 mothers were assisted to the extent of \$10.00 each, and 351 doctors, 6 nurses, and 11 hospitals received \$15.00 each, making a total of \$10,032.00. Whether these benefits fulfil the expectations, and whether this province should enter upon such a scheme, are matters for investigation and debate.

The community should have a direct interest in this problem of maternal mortality. The co-operation of Women's Institutes should be sought, municipalities should be urged to provide public

deviates from the normal is illustrated by Figs 1 and 2, which have been modified from those given by Abbott and Dawson⁸ in their valuable classification

CASE REPORT

R B, male, aged 29, was admitted to King Edward Memorial Hospital, Winnipeg, on February 10, 1926, with a diagnosis of pulmonary tuberculosis and congenital heart disease (right ventricular hypertrophy, probably interventricular communication)

Between the years 1913 and 1926 he had been treated at intervals in the Winnipeg General Hospital as an out patient and as an in patient. Complete general and special cardio vascular examinations were made

Family History—Father died at 46, of a "chest condition", mother died at 36, of dropsy. Two sisters were alive and well, one sister died from an unknown cause, two brothers died in infancy from an unknown cause, and two brothers, aged 20 and 40 respectively, were alive and well

Personal History—He was born on the boat coming to Canada, of Polish parents. He was never able to do much work on account of his heart condition, and had always been receiving medical attention. He always slept 7 to 8 hours nightly (with three pillows), his general activity was much restricted. He did not use alcohol or tobacco. Small pox in 1910

Present Illness—In 1914 he was in the Winnipeg General Hospital with a sore back. Following his discharge he felt weak and became tired easily. He was unable to take part in any of his former outdoor activities. This continued until 1918 when his feet began to swell and ulcers appeared on his legs. As these healed, others came. From 1923 his weakness gradually became more marked and he was unable to do any work. In the summer of 1924, following some over exertion, he had a chill. A few days later he began to cough. The cough was slight at first and non productive

EXTRACTS FROM WINNIPEG GENERAL HOSPITAL HISTORY

"A striking feature was the marked clubbing of the fingers and toes. The nose was bulbous and the lips pendulous. Cyanosis was extreme, the entire body being of a muddy, bluish colour. The apex beat (maximum impulse) was $5\frac{1}{4}$ inches from median line, in the sixth left interspace. The outer point of impulse was $5\frac{1}{4}$ inches from the median line in the sixth interspace. Systolic and faint diastolic murmurs were audible. The maximum systolic murmur was just to the left of the sternum, in 3rd and 4th intercostal spaces. The artery walls were not palpable. Pulse, 70-90, was small, regular, not collapsing nor showing any deficit. Polycythemia was marked, the red blood count varying

FIG 3—Electrocardiograph tracing (Retouched to facilitate reproduction)

from 10,160,000 to 8,500,000, hæmoglobin, 100 per cent. The Wassermann was negative. Urine, negative. No record of blood pressure findings. An electrocardiogram (Fig 3), taken August, 1924, showed the following peculiarities—

"First lead, exaggerated 'S' wave. Second lead, negative. Third lead, sharp inverted 'T' wave. Right ventricular preponderance.

"The condition was diagnosed as that of 'congenital heart, with probably interventricular communication' (Dr A. J. BurrIDGE)"

A radiogram, taken December, 1925, is shown in Fig 4

The report of the radiographer (Dr J. C. McMillan) was that the heart and great vessels showed marked increase, and that there were definite changes in the lungs suggesting tuberculous lesions. It is to be regretted that a fluoroscopic examination was not made nor a left anterior oblique plate taken, because the writers are satisfied that the presence of an anomalous right arch would have been demonstrated

FIG 4—Radiogram. Marked increase in the size of the heart both to right and left, and of great vessels to right of median line. Enlargement of the shadow at hilum of right lung (Assman's sign), indicating dilated pulmonary vessels

During 1925 the severity of the cough increased, with considerable expectoration. During the last three months expectoration amounted to half a box per day, with a large amount of blood. The loss of weight was rapid. He reported to the Winnipeg General Hospital where his sputum was found to contain tubercle bacilli. He was therefore transferred to King Edward Hospital

The history on admission to King Edward Hospital showed that he had had a cough for one year, with expectoration for the last three months, he spat up three or four mouthfuls of blood every time he coughed. He had lost twenty five pounds in the last two years, weakness and malaise had been progressively worse since 1914, he had had dyspnoea for as long as he could remember, cyanosis, clubbing of the fingers and toes, and palpitation

Examination there showed marked cyanosis and clubbing of the fingers, weight, 150 pounds, height, 5 ft. 6 inches. His condition was diagnosed as that of an advanced pulmonary tuberculosis, showing marked involvement of the right upper lobe, with some dullness over the left upper lobe and late post tussic crepitations on both sides. He died August 12, 1926

Post Mortem Examination—The general characteristics were as previously noted in the history. Especially marked were multiple scars from old ulcerations on the legs, and the clubbing of the fingers and toes. On removing the sternum one was impressed with the width of the pericardial sac. Both pleural cavities were obliterated and in the right there was extensive fibrous adhesion. Both lungs showed old tuberculous lesions there being cavitation and scarring in both apices. An extensive miliary tuberculosis had invaded the remaining parenchyma of both lungs.

HEART AND GREAT VESSELS The heart was a large muscular organ and one was impressed by the degree of ventricular hypertrophy, the transverse diameter being 12 cm and the distance from coronary sulcus to apex 10 cm. The muscular portion appeared to be composed of both ventricles equally, separated by a prominent inter-ventricular sulcus. Arising from the base of the heart only one great vessel was to be seen, which measured 3.5 cm. in diameter. This vessel curved to the right, giving off in the following order the left innominate, right carotid and right subclavian arteries, and descended on the right side of the vertebral column behind the right bronchus. The pulmonary stem was not present. The arteries entering the hila of both lungs were seen to be branches from a trunk which arose from the descending portion of the aorta. This trunk passed upwards from behind the right bronchus. An additional small artery arose below this trunk from the anterior aspect of the aorta, and passed to the lower lobe of the left lung. A large thin walled, trumpet shaped vessel emerged from the left posterior wall of the right aortic trunk, the size of its communication with the aorta being 0.5 cm in diameter, and flared out to empty into the hilum of the right lung. The venous return from the lungs and the systemic return to the heart were normal. The heart when opened showed marked hypertrophy of the ventricular walls, the right being 2 cm and the left 1.5 cm. thick. The two ventricles communicated freely with each other over the top of the interventricular septum, which presented a smooth upper margin, completely covered with endocardium. Arising from the base of the heart above the upper free border of the interventricular septum was the thick walled aorta. The left atrium was normal in size, the right atrium was greatly dilated.

Spleen, weight 450 grm. Liver, weight 2,200 grm.
Kidneys, weight 220 grm. Remaining viscera negative.

FIG 5—The heart laid open from behind. The thick walled ventricles and interventricular septum are clearly seen. Note the hematoma on the aortic cusp.

FIG 6—The aorta, trachea, and esophagus. Note the trunk (left aortic root) arising from the descending aorta giving branches to hila of lungs. The communication between the dilated right pulmonary artery and the aorta by means of the minute ductus arteriosus can be seen. A portion of the right lung and an enlarged hilum gland are present.

EMBRYOLOGY OF THE CONDITION

The embryological explanation of these anomalies is of interest.

In the human embryo there develop six branchial arteries which pass dorsally. These arteries when fully formed are arranged as illustrated in Fig 7.

The next step in development is the disappearance of the vessels of the first arch. A little later the second branchial vessel also degenerates. Then that portion of the dorsal trunk which intervenes between the third and fourth branchial vessels disappears, so that the dorsal trunk anterior to the third branchial arch is cut off from its connection with the dorsal aorta and forms, together with the vessel of the third arch, the internal carotid. The ventral trunk anterior to the point of origin of the third vessel becomes the external carotid, and the portion intervening between the third and fourth vessels becomes the common carotid. The rudimentary fifth vessel vanishes, as did the first and second, but the fourth persists to form an aortic arch, there being at this stage in development two complete aortic arches. From the sixth arch the pulmonary arteries are de-

FIG 7—Diagram illustrating the primary arrangement of the branchial arch vessels.
a, Aorta, ab aortic bulb, ec external carotid, ic, internal carotid, sc subclavian, I-VI, branchial arch vessels (After McMurrich)

lived That portion of the right sixth arch which intervenes between the point of origin of the pulmonary artery and the right aortic arch disappears, while the corresponding portion on the left side persists until after birth, forming the ductus arteriosus, as shown in Fig 8

A comparison of Fig 9 (R B) with Fig 8 (normal) illustrates well the unusual arrangement of the arches which were present The right aortic arch has persisted and it therefore gives rise to the following branches, a left innominate, a right common carotid and a right subclavian The distal portion of the left aortic arch has disappeared The proximal portion of the left aortic arch has persisted and from it are given off numerous branches which pass to the hila of both lungs, and are responsible for the aeration of the blood We believe that these branches are in reality hypertrophied bronchials Meckel first suggested the possibility that dilated bronchials might replace pulmonary arteries when the ductus arteriosus was completely closed

The sixth branchial arch is of interest There

FIG 9—The variations of branchial arch vessels in R. B

is complete pulmonary atresia. The ductus arteriosus has persisted and maintained a very small opening with the arch of the aorta. This passes to the right and becomes continuous with a trumpet-shaped thin-walled right pulmonary artery which enters the hilum of the right lung. There is no left pulmonary artery.

SUMMARY

This case presents the following cardiac anomalies:

- 1 Incomplete double aortic arch (intermediate portion of the left arch being deficient)
- 2 Dextroposition of the aorta
- 3 Pulmonary atresia
- 4 Ductus arteriosus, persisting as a small vessel communicating only with the hilum of the right lung by way of the right pulmonary artery
- 5 Pulmonic circulation maintained by means of hypertrophied bronchials, branches of the left aortic root
- 6 Incomplete ventricular septum, the endocardial cushions having failed to fuse

The following observations of clinical interest may be made. Nature had attempted to compensate for the deficient aeration of the blood. The red cells were 200 per cent, hæmoglobin 100 per cent, therefore the blood had the normal carrying capacity for oxygen and one wonders whether the increase in red cells was a compensatory arrangement.

The blood pressure of the pulmonic circulation could have been little, if any, below that of the systemic.

II DETAILED DESCRIPTION OF HEART AND AORTA

(MAUDE E. ABBOTT)

Heart

The heart is a heavy muscular organ with a broad ventricular part measuring 12 cm across at its base, and 10 cm in length, with rounded slightly bifid apex, composed about equally of both ventricles. From about the middle of its base arises the greatly dilated and thick-walled aorta between the much enlarged right auricle and smaller left auricle, both of which are visible anteriorly. At first sight no other vessel is seen, but examination reveals a small thin-walled pulmonary artery, 2 cm long and 1 cm wide, which emerges from the musculature just

in front of the root of the aorta and passes obliquely up and to the left, dividing into two small branches. It is thus patent in its distal portion but is completely closed at its origin from the heart just below the valve, which is represented by a tiny rudimentary fold of fibrous tissue separating two minute sinuses.

The heart has been laid open from behind by incisions through auricle and ventricle, leaving the intact interventricular septum exposed. This is a massive muscular structure, nearly 2 cm thick in its lower portion, and incomplete above, where it ends in a rounded muscular free border which forms the lower margin of a huge defect, 4 cm long by 2 cm wide, extending from just in front of the pars membranacea septi to the junction of the anterior and left posterior (right and left coronary) aortic cusps. The endocardium covering the free border of the defective septum is thickened and the septal cusp of the tricuspid valve takes origin in part from it. The dilated aorta, which is 9 cm in circumference and very thick-walled, arises above the defect, 4 cm of its lumen lying in the left, and 5 cm in the right ventricle (*rechtslage* or dextroposition), it has three semilunar cusps, of which two, the right and left coronary, are very large, 3 cm in length, screening roomy sinuses of Valsalva, toward the upper border of which lie the large and patulous right and left coronaries, the contiguous halves of these two cusps are extensively fenestrated and behind the anterior one in the depths of its sinus is a small calcareous nodule suggesting an obliterated raphe. The third aortic segment (right posterior or free cusp) is much smaller than the other two and has a peculiar interwoven structure, it is fused with the adjacent half of the anterior (right coronary) cusp and between the layers of the commissure so formed is a large hæmatoma, apparently the result of the impact of the current of blood entering from the right auricle and impinging at this point on its way into the aorta. Just anterior to this cusp in the depths of the angle formed between the anterior wall of the heart and the base of the defective interventricular septum is a short muscular partition 0.5 cm long, which is the posterior wall of the rudimentary pulmonary conus, which admits a small probe and then ends blindly just below the obliterated pulmonary orifice.

The tricuspid valve lies posteriorly and to the

right of this rudimentary conus. Its septal cusp is of normal shape and structure, but arises in part from the posterior part of the upper border of the defective interventricular septum, and in part from the adjacent septum. Its marginal and infundibular cusps are partly merged with each other and the latter has many anomalous fenestrations, behind the attachment of the marginal cusp to the myocardium is a calcareous mass the size of a bean. The muscle of the right ventricle is enormously hypertrophied (1.5 to 2 cm thick), but its cavity is only slightly enlarged (simple hypertrophy). The left ventricle on the other hand is very roomy, and its walls are also much thickened (1.5 cm), though less than on the right side. The mitral valve is normal and the left auricle is of normal size, but the right auricle is greatly dilated with hypertrophied walls. The auricular septum is entire and the foramen ovale is completely closed.

The Aortic Arch and Descending Thoracic Aorta

The specimen consists of a right aortic arch and its branches with the trachea at its bifurcation and the right bronchus attached to a portion of the hilum of the right lung, and the œsophagus. The ascending arch has been cut off about 3 cm above the heart and at this point the lumen is 3.5 cm in diameter. It curves to the right instead of to the left, descending on the right side behind the right bronchus and gives off, in the following order, the left innominate, right carotid and right subclavian arteries, diminishing gently as it does so, so that just after the origin of the latter vessel it is 2.5 cm in diameter. About 1.5 cm below this point there emerges from the left posterior wall or the right aortic trunk a thin-walled tube about 0.75 cm in diameter, which expands about 1 cm from its origin in a bulbous fashion and presents an orifice 1.2 cm in diameter of a vessel which apparently entered it and which may have been the right branch of the atresic pulmonary artery. After this opening, the thin-walled vessel resumes its previous calibre and then dilates again, gradually expanding in trumpet fashion until after a course of 9 cm it presents a flared-out end 3 cm across, which has been cut off by the pathologist, who states that at this point it entered the hilum of the right lung and had no connection whatever with the

left lung, apparently functioning as a right pulmonary artery. Internally, this cut end presents an atheromatous surface. At a point 2.5 cm below the entrance of this curious structure the descending aorta gives off from its left wall a thick-walled trunk of about equal diameter to itself (2 cm), which curves upward behind the right bronchus occupying the position of the primitive left dorsal aorta, and is undoubtedly a persistence of the proximal part of this structure (persistent left aortic root). About 1 cm from its origin this anomalous left aortic trunk bifurcates into two branches, the superior, larger one, curves obliquely upward to the left giving off in its course four branches, one of which enters the hilum of the right lung anteriorly, and the other three (which are cut off) probably passed to the left lung, and served as bronchial arteries, the final distribution of this superior branch of the left aortic root is unknown, for it has been cut off about 4 cm from its origin, but from its direction it probably supplied a part of the distribution of the left subclavian artery. The inferior and smaller branch of the left aortic root is about the size of a slate-pencil, passes into the hilum of the right lung behind the right bronchus, it undoubtedly functioned as a right bronchial artery. About 1.5 cm below the left aortic root another anomalous vessel emerges from the left wall of the descending aorta, which probably also went to the left lung. The œsophagus lies behind and to the left of the aorta in its entire length. The trachea lies in front of the œsophagus and behind the transverse arch, but after its bifurcation the right bronchus passes outward to the right lung in front of the left aortic root, the upper branch of which emerges at the bifurcation of the trachea and passes upward and to the left in front of the left bronchus to its destination on the left side of the body.

REMARKS

This rare case is of special interest because of the remarkable adaptations which had facilitated the course of the blood and so permitted the patient to attain a relatively mature age, in the presence of a pulmonary atresia and suppression of the normal development of the left aortic arches, which were apparently the primary lesions. These adaptations are IN THE HEART, (a) The incomplete development of the inter-

ventricular septum and the dextroposition of the aorta, which vessel received all the venous blood from the right chambers above the defective septum, as well as the arterial blood from the left side, (b) the enormous hypertrophy of the musculature of the right ventricle which propelled the blood from the right auricle, first into the stenosed pulmonary conus and then into the aorta, and the hypertrophy and dilatation of the left ventricle which assisted the right in pushing the blood through the aorta into the lungs. IN THE AORTA, (a) The large varicose trumpet-shaped tube which apparently represented the patent ductus and anomalous right pulmonary artery, and evidently carried the mixed venous and arterial blood from the heart to the right lung for aeration, (b) The rich

arterial supply to both lungs from the persistent left aortic root apparently fulfilling the function of the bronchial arteries, (c) The anomalous vessel from the descending thoracic aorta, which from its direction probably furnished an additional path for blood to the left lung

THE TREATMENT OF EPILEPSY*

By C H PRATT, M B,

Assistant Physician, Ontario Hospital

Woodstock

THIS paper will have to do, primarily, with the treatment of epilepsy as it is carried out at the Ontario Hospital, Woodstock, with special reference to the value of Phenobarbital (Luminal), in the larger dosage, in bringing about the arrest of seizures

Provincial hospital treatment along modern lines appears to be the best means of handling the epileptic problem. The ideal arrangement would be to have all the epileptics of the province treated in one hospital. Accommodation should be provided for two main groups—

1 The defective, demented, and the psychotic epileptics

2 The sane epileptics

The buildings for the two sexes are best kept widely separated on the same grounds, being divided by some natural barrier, such as a stream or body of water. Ample accommodation is necessary, to allow of segregation according to mentality and behaviour. The necessity of this is obvious to the most casual observer who visits the wards where such a provision does not obtain

For purposes of treatment, all admissions

would resolve themselves into one of two main groups, based mainly on prognosis (1) those requiring protracted treatment and care, (2) those for temporary hospitalization

The first group embraces those who are (a) epileptic, on a mentally defective basis, (b) demented, secondarily to chronic epilepsy, and (c) the epileptic psychotic patients, in whom the epilepsy *per se* forms a minor part of the whole picture. Even though their seizures were arrested they would be unable to earn a livelihood in a competitive labour market. Some, owing to asocial habits or abnormal behaviour reactions, cannot be cared for in the home. For this type of patient proper nourishment, regularity of rest, work and recreation with direct supervision under hygienic conditions, together with moderate medicinal treatment, would do wonders towards making them a happy, contented and useful people. This is in reality the colony system.

Under the second head comes that type of patient who is commonly called the "sane epileptic," who, if his seizures were arrested, could take his place in the economic world, and whose intelligence is of such an order that he would carry out, after he left the hospital, the routine

*Read at the Spring Meeting of the Ontario Neuro-psychiatric Association, London, Ont., on June 11th, 1928

factors in so-called reflex epileptic types Zabriskie⁶ states, "it is fairly safe to say that whenever the diagnostic criteria of production of a fit by stimulation of the irritative focus, etc., are satisfied, removal of the focus will cure the epilepsy." In accepting his statement one should take into consideration cases of long standing that may have acquired the epileptic habit of spontaneous discharge, in which this would not obtain.

A cold shower on rising, followed by a brisk rubdown, is to be particularly recommended for epileptic patients of the more or less rugged type. Full co-operation of the patient is desirable here, and time is well spent in securing such co-operation. He enters into it with much more zest and enthusiasm, if he feels he is doing so of his own free will and accord, rather than under compulsion. Once he commences, he understands it is to be routine. No fads are indulged in. He is made to feel that when he leaves Woodstock he can carry his healthful practices over into his life outside. The training he gets in the care of himself and others is comparable to that secured in sanatoria for the treatment of tuberculosis in the early stages. He is made to feel the importance of general health measures, regularity of habits, and the strict adherence to therapeutic measures laid down for him.

The diet is simple, readily digestible and anti-constipating. Bran is incorporated in the morning meal. The principal meal is at midday. Animal protein, in replacement amounts, is given in some form at this meal, together with abundance of fresh vegetables in season. Here again the food is not widely different to that in his own home. The ketogenic dietetic treatment of epilepsy runs foul of this principle, and one that there is difficulty in having the patient consistently follow after he leaves the hospital. This is an important point in dealing with the group under consideration.

An outline of this form of treatment may be given at this point. Periods of starvation have been employed in the treatment of epilepsy, being based on the observation, that, during fasting and acute febrile illnesses, the seizures were markedly lessened. In the chemical study of patients so treated, the most striking changes found were a lowered blood sugar, a ketosis-acidosis, and a slight lowering of the carbon-dioxide combining power of the blood.

Wilder,⁷ and later Peterman,⁸ produced these same chemical changes by developing a so-called

"ketogenic diet." By keeping the carbohydrates and protein low and the fat content in the diet high, insufficient glucose is available for complete oxidation of the fat into its normal end-products, carbon dioxide and water. This incomplete combustion results in the liberation of intermediate products, the ketone bodies, chiefly aceto-acetic acid, which break up into acetone and beta-oxybutyric acid, present in the blood in the form of salts, and are excreted in the breath and urine. This is the condition of ketosis-acidosis.

The carbohydrates, fats and proteins are classified as ketogenic and antiketogenic substances; the former are substances producing aceto-acetic acid in the absence of glucose bodies, the latter are substances producing glucose bodies which prevent the formation of ketone bodies. The values are as follows—

	<i>Ketogenic</i>	<i>Antiketogenic</i>
Carbohydrates	0%	100%
Fats	86% (Approx.)	14% (Approx.)
Protein	33% (Approx.)	66% (Approx.)

Talbot,⁹ in working out diets, regards fat as 100 per cent ketogenic, carbohydrates 100 per cent antiketogenic, and protein half and half. According to these values, a proportion of ketogenic to antiketogenic foods in the usual diet is about 1 to 4. If the relationship of the ketogenic to the antiketogenic foods is 1.5 to 1, ketosis does not develop. "A 1.5 to 1 ratio means that the diet contains 1.5 grams of fat for each gram of carbohydrates and protein (combined)." "The protein allowance for any patient is one gram for each kilogram of the patient's expected body weight. The total caloric needs are 50 per cent above the basal requirements (Talbot¹⁰)." "With an increase of this ratio to 2 to 1 or more, a ketosis develops, and the higher the ratio the greater is the ketosis. Coincidentally with the marked ketonuria resulting from the diets of a higher ketogenic ratio, a reduction or cessation of attacks has occurred (Talbot, Metcalf and Moriarty¹¹)."

The changes in the diet are made slowly at about one to two week intervals. A 4 to 1 ratio is generally required before the symptoms completely disappear. This usually takes a period of two months. The patient is kept on the diet until he is free from seizures for six months. The diet is then gradually relaxed by increasing the carbohydrates 10 grams at a time, and reducing the fat in the corresponding amounts, maintaining the same value in caloric intake (Talbot⁹).

These changes are continued until the child is on a normal diet with a limited amount of carbohydrates. It is necessary always to exclude candy and other sweets from the final diet. Luther¹² states, "it is too early as yet to reach definite conclusions as to the permanence of the relief." Talbot⁹ reports complete symptomatic relief in at least 33 per cent of children, and definite improvement in nearly three-quarters. The results are accordingly good in "petit mal" and "grand mal," but less satisfactory in the adult than in the child. Excessive intake of sweets is followed by attacks. Talbot, Metcalf and Moriarty,¹³ who are very enthusiastic over this method of treatment, state, "The difficulties of the diet in epilepsy are the same as those experienced in the treatment of diabetes mellitus before the advent of insulin, good and bad results depending in large part upon how strictly and accurately the diet is followed. In both instances indiscretions in carbohydrates are usually followed by relapses."

The *modus operandi* of ketosis-acidosis in bringing about the clinical improvement is still a matter of conjecture. The view that the freedom from attacks is due mainly to the hypoglycemia produced is not substantiated by Talbot, Metcalf and Moriarty,¹³ in a three months' study of insulin therapy in conjunction with an ordinary diet. That the anæsthetic action of acetone may be the cause of the improvement is admitted by Talbot⁹. If the arrest of seizures is brought about by the anæsthetic action of acetone, the patient producing his own drug by a method of diet admittedly difficult to maintain, one might well adhere to drug treatment, allowing the patient more or less freedom of action as to diet after he leaves hospital. A highly complicated diet is certainly not compatible with the facilities at hand for an adult taking his place in this work-a-day world. If the future proves that the ketogenic diet brings about a permanent arrest of the seizures, even though hospital treatment of one or two years is necessary, it would be worth while indeed.

The value of the salts of bromine has long been recognized in the treatment of this disease. Turner¹⁵ regards large doses of bromides as neither necessary nor effectual. Both the amount of the dose, frequency and time of administration, must be gauged by a study of individual cases. He does not look with favour on prescribing fifteen grain doses three times daily. The night dose is to be preferred.

The three common bromine salts of potassium, sodium and ammonium are those most commonly used. The potassium and sodium salts are the most efficacious according to Turner,¹⁵ and may be prescribed alone or in combination. The dosage of the combined salts must not exceed 45 to 60 grains in the 24 hours.

Gowers⁴ introduced sodium bichlorate in the treatment of epilepsy in certain cases where the bromides were of little value. This has been used at Woodstock in combination with strontium bromide, with favourable results.

The main disadvantages associated with the use of bromides are the skin eruptions, and a dulling or blunting of the faculties. This has been our experience especially in pushing the drug to sufficient dosage to bring about the complete arrest of seizures. The results obtained from the use of luminal have been comparatively so outstanding that at the present we use bromides only to a small extent. We have found bromides useful in moderate doses in a few cases where luminal, in sufficient dosage to control the seizures, was not well borne. We were not able to bring about an arrest of seizures in these cases however.

On this continent luminal enjoys an increasing popularity in the treatment of epilepsy, since its introduction from Germany, more than fifteen years ago, as an antispasmodic and sedative. It is a hypnotic in large doses. The threshold of hypnosis varies markedly in individual cases of epilepsy, and, in our experience at the Ontario Hospital, is much higher than in non-epileptics.

Dercum,¹⁶ in one of the earliest reports of an extensive use of the drug in epilepsy, found it exercised a remarkable control over the seizures. He limited the dosage to a maximum of 3 grains per day. No deleterious influence upon the mental life of the patient was observed. Again in 1922, he reported¹⁷ that "in the ordinary so called 'essential' form of epilepsy no remedy has proved of so much value as luminal." He limited the dosage to 1 to 1½ grains daily, given in one dose at bedtime. A great improvement was noticed in the general health of the patients so treated.

Cobb¹⁸ believes that luminal is a very useful drug in the treatment of epilepsy. He considers it unsafe to give more than 1½ grain doses, which should not be repeated more than once in the twenty-four hours.

Patterson, Daman and Levi,¹⁹ of Sonyea, in reporting the results of luminal therapy in a

but the change in general is remarkable. Salivation stops, cerebration is quickened, the physical strength returns, and the patient appears to be practically normal.

The method of administration of luminal at Woodstock is by the oral route. The dosage is divided according to whether the seizures are nocturnal or diurnal. In the majority of cases luminal is best tolerated given in the morning and evening. In some cases, where the morning dose of 3 grains was divided and given in the morning and at noon, the patient complained of drowsiness. This was not apparent when he received the full dose in the morning, as well as his evening dose. The luminal tablets are given at breakfast, in some cases at noon, and at the evening meal at 5 to 6 o'clock. This early administration of the evening dose does away in many cases with drowsiness the following morning.

Paterson, Damon and Levi,¹⁹ in investigating the other methods of administration of luminal in the form of its sodium salt, *viz*, subcutaneous, intravenous, and intraspinal, found that the intravenous method was the most rapid in bringing about therapeutic effects and was the method of choice in status epilepticus. At Woodstock, at present, in these cases we rely on chloroform anaesthesia to the surgical stage, together with double doses of H M C No 1 to continue its effects, or a chloral enema (grains 30-60). The results have been very satisfactory.

We are in agreement with Paterson, Daman and Levi,¹⁹ who state that, as luminal is a pol-

lative measure, it must not supplant attention to general hygienic measures, to improvement of the patient's general condition, the inculcation of regular habits, and medicinal treatments as indicated.

Constipation is the rule rather than the exception in our new cases. Obviously, this condition must be remedied before the best results are obtainable from luminal therapy. On admission to the wards the patient, if constipated, is given a large simple soap enema, and oleum ricini (oz 1½) at bed time. This is followed every night by Russian oil in sufficient quantities, together with magnesium sulphate once weekly. We do not put him on luminal, however, until he "registers," that is to say, he is allowed to have a few seizures for record and purposes of comparison.

In female patients changes in menstrual activity must be closely watched. Amenorrhea must be immediately treated by general and specific medicinal means, as seizures are very apt to recur during disturbances of menstrual function.

Many writers point out the beneficial effects of luminal therapy on the general behaviour reactions of epileptics. The patients so treated become more congenial, energetic and co-operative. This is especially true in cases of arrest in the sane epileptic. The very fact that his hopes are realized, and this type of patient is nearly always very hopeful, makes a marked difference in him generally. Introspection becomes less marked as his anxieties disappear. Self-confi-

Treatment—August 24, 1925, Luminal grs 1½, q h s

dence is gradually re-established, and finally, after a year or so of freedom from attacks, he wants to again go out into the world to earn a livelihood. The difficulty in most cases is to curb this natural tendency long enough to make certain of the arrest.

When the arrest is convincingly established the patient's family physician is given an outline of the treatment and care necessary for the continued arrest of the seizures. We ask to be consulted before any change in treatment, such as the gradual reduction in the dosage of luminal. The patient is also given a detailed outline of treatment, diet, and hygienic measures. He is then allowed out on probation, reporting his progress once a month until discharged, then once every six months. This has been a very useful method in following up results. Co-operation in this regard has been particularly satisfactory.

The following charts and case reports typify the results in our experience in the treatment of epilepsy at Woodstock.

CASE 1

(Reg. No. 530), A C, female, aged 52, admitted August 9, 1917.

Hereditary taint nil. Fits at teething period nil. Normal child. Injury at 10 years (kicked on the back of the head by a horse). Onset at 13 years, puberty. On admission grand-mal attacks about once monthly, mentality good. Treatment Luminal, grains $1\frac{1}{2}$, begun August 24th, 1925. Result Seizures arrested since March 25, 1926, mentality normal, no by-effects, about to be discharged. (See table IV).

CASE 6

(Reg. No. 802), E R, male, aged 11, admitted December 29, 1924.

Hereditary taint nil, father intemperate. Fits at teething slight. Injury Acute poliomyelitis at 4 months, ill a month, badly scalded at 7 years, excessive scarring. Onset at 8 years, while going to school, grand-mal. On admission Having fits nearly every day, spoilt child, dull and below normal mentally. Treatment Attended out-patient clinics at Montreal and Toronto. Was on small doses of luminal at that time. Treatment as below. Results No apparent result from luminal in small doses, increased dosage brought about arrest, no by- or after-effects, mentality cleared, normal boy, played an excellent game of ball. Is now discharged on treatment and is going to school, good progress reports. (See table V).

CASE 7

(Reg No 729), C M, male, aged 29, admitted July 17, 1922

Hereditary taint nil Fits at teething nil Injury Struck on nose (at 17 years) by broken end of golf club, nose broken, unconscious for a short period Onset at 18 years, during college course, had one seizure, then was free for 14 months, then attacks every 6-8 days, grand-mal, no aura On admission mentality fair, rather dull, was on bromides, seizures, 2-3 per month Treatment As below Complained of mental sluggishness when put on bromide in small doses Luminal was finally used alone, with anti-constipation measures, cold shower on rising May 10, 1926, increased margin of safety Results No by- or after-effects, mentality returned to normal, good general health Built his own radio set while in hospital Discharged June, 1927, excellent progress reports, free of seizures, working outdoors (See Table VI)

CONCLUSIONS

1 A confirmed arrest of epileptic seizures can best be brought about by hospital treatment

2 More arrests of seizures are established by continued luminal therapy in moderate doses (3 to 6 grains daily, [0.2 to 0.4 gram]) than by smaller doses ($\frac{3}{4}$ to $1\frac{1}{2}$ grains daily [0.05 to 0.1 gram])

3 The by- or after-effects are but little more often encountered under the use of luminal in moderate doses than under small doses

4 The dose of luminal in the treatment of the epilepsies is limited only by the dosage that can be reached without producing by- or after-effects

5 The "grand-mal" attacks are more amenable to luminal therapy than the "petit-mal."

6 The cessation of attacks checks the mental deterioration associated with continued attacks

7 Though luminal therapy in small doses is

occasionally accompanied by an increase of epileptic attacks larger dosage often results in an arrest in these cases

8 In the sane epileptic, if the seizures are arrested for a considerable period of time, he is again fit to lead a more or less normal existence

9 As luminal therapy is a palliative rather than a curative measure, it should not supplant attention to general hygienic measures, to improvement in the patient's general physical health, regular habits and other medicinal treatments as indicated, in the endeavour to bring about permanent arrest of the attacks

Myotonia from Calcium Deficiency—Charles E. Kiely reports the case of a man, aged 26, who complained chiefly of pain in the small of the back and stiffness of the calf muscles. The significant history was that in 1921 while playing basket ball he had been struck in the small of the back by another player's knee, and since had suffered from pain in that region. In November of the same year his shin bones became sore and jumping was particularly painful. In the fall of 1922, spasm of the calf muscles began. This appeared not with the imitation of movement but after severe effort. Other leg muscles became involved, but there has been no involvement of the trunk or arms at any time. Only rest and massage would relieve the spasm. There was no history of any muscular disease in three generations of his family, to his best knowledge. He had had no thyroidectomy or other likely source of injury to the parathyroid. There was no history of spasmodic in childhood. He was obliged to discontinue athletics and dancing. His work involved climbing two hundred steps in one case and

this became almost impossible. May, 19, 1927 the blood calcium report was 8.5 mg per hundred cubic centimetres. Blood uric acid, uric dextrose and creatinine were all within normal limits. Electrical reaction showed a polar reversal over the tibial nerve at a single examination but was normal the next day before the beginning of treatment. The contraction to the electric current was rather slower than usual but in no sense tetanic. No attempt was made to induce a wave of myotonia by passing a current from one extremity of the body to the other, as too painful a current is required. The patient was given calcium lactate, 0.325 gm, three times a day. He reported prompt improvement. Electrical reactions were normal. November 14, 1927, he returned complaining of moderate exacerbation of stiffness. He had been taking calcium lactate only twice daily for several weeks. The blood calcium was 13.35. He was advised to increase his calcium to the original dose and did so reporting January 25, 1928, that he was entirely relieved.—*J Am M Ass*, August 11, 1928

SOME COMMON MISTAKES IN THE DIAGNOSIS AND THERAPY OF DISEASES OF CHILDREN*

BY ALAN BROWN, M B ,

Toronto

"IT is written that there 'abideth faith, hope charity, these three, but the greatest of these is charity' And so in medicine we have diagnosis, which is a matter of faith, prognosis, which is a question of hope, and treatment, which is only too often an affair of charity but the greatest of these is diagnosis For, without accurate diagnosis, it is impossible to forecast the course and outcome of a disease or to treat it satisfactorily Indeed, as someone has truly said, 'the first part of treatment is diagnosis, and the second, diagnosis, and the third, diagnosis' I need make no apology therefore, for directing your attention to some reflections on such an important subject on this occasion" (Hutchison, R, *Brit M J*, 1928, 1, 335)

A review of the records of our hospital reveals the fact that certain diseases are very frequently overlooked by the physician in charge of the patient before his admission to the hospital In the succeeding paragraphs your attention will be directed to these conditions, and the essential points in their diagnosis and treatment will be considered briefly, beginning first with new-born infants

HÆMORRHAGIC DISEASE OF THE NEW-BORN

This disease is characterized by spontaneous hæmorrhage from one or more parts of the body, and is of unknown etiology

The hæmorrhages occur most frequently from the gastro-intestinal tract, as evidenced by bloody stools or vomited blood The blood may be tarry, dark brown, or bright red The next most frequent site of bleeding is the umbilicus In occasional cases the bleeding may be intracranial, or may occur from the nose, conjunctiva, or under the skin The bleeding and clotting time is usually prolonged, though in some instances it may be normal The most frequent time of onset is the third day of life The condition occurs with decreasing frequency, until it is practically never encountered after the

twelfth day Hæmorrhages at this late date are usually the results of general sepsis or syphilis The treatment consists in the immediate transfusion of 15 c c per pound of body weight of whole blood The blood of ungrouped donors should not be used If facilities are not available for transfusion the intramuscular injection of a total of 20 to 40 c c of ungrouped blood may be given at three or four different sites

CYANOSIS IN THE NEW-BORN

Cyanosis in the new-born may result from atelectasis, intracranial hæmorrhage, congenital defect of the heart, or enlarged thymus Atelectasis, which is an incomplete expansion of the lungs, usually occurs in premature or debilitated infants The cyanosis is intermittent Examination of the lungs frequently discloses nothing abnormal, unless the atelectasis occurs in a portion of one lung over which area a diminished air entry can be distinguished The treatment consists in stimulating the infant to cry vigorously at frequent intervals Intracranial hæmorrhage usually results from the tearing of blood vessels in the falx or tentorium In mild cases the only symptoms are slight drowsiness and refusal to nurse properly In the more severe cases there may be convulsions, as well as interference with the pulse and respirations The cyanosis is usually constant The only treatment is repeated lumbar puncture to drain off the blood Congenital heart defects can be recognized on routine examination of the heart Cyanosis, if due to a heart defect, is constant There is no specific treatment Cyanosis due to an enlarged thymus is intermittent

ENLARGED THYMUS

This condition is due to a hypersecretion of an enlarged thymus gland The most frequent symptoms of the condition are, sudden attacks of cyanosis, or pallor, breath-holding spells, convulsions, and slight difficulty in breathing similar to that produced by a mild degree of laryngeal obstruction In new-born infants this difficulty

* Read at the 59th annual meeting of the Canadian Medical Association, Charlottetown, P E.I., June, 1928

in breathing may be so marked in the severe cases that the symptoms resemble asthma. Although retrosternal dullness may be detected at the level of the first and second intercostal spaces, a definite diagnosis can only be made by means of an x-ray plate. In infants with only slight enlargement the shadow will extend just past the lateral borders of the sternum, while in marked cases the shadow will extend many centimetres on each side of the mid-line. At the present time we do not know the exact variations in the size of the gland, but we do know that infants with only a slight enlargement have very mild symptoms if any. We have never seen a severe or fatal case without a marked enlargement of the gland. Care must be taken in the diagnosis of enlarged thymus, as at the present time there is a tendency to consider many unexplained symptoms as due to this disease. The treatment consists in repeated exposure to x-rays, and this, to the best of our knowledge, will absolutely cure the condition.

INANITION FEVER

Inanition fever occurs in new-born infants and is due to a lack of fluid intake at a period when the heat-regulating mechanism is unstable. The objective symptoms are, fever, excessive initial loss of weight, some loss of elasticity of the skin, dry mucous membranes, and frequently an odour of acetone on the breath. The condition usually occurs during the third, fourth or fifth day of life in those cases in which the breast milk supply has not yet been established. The treatment consists in a rectal irrigation of water, and the administration of a suitable artificial feeding, until a sufficient supply of breast milk is available. The temperature will drop in the course of a few hours. Care must be taken not to mistake an infective process for this condition.

PYLORIC STENOSIS

Pyloric stenosis is a marked hypertrophy of the circular muscle fibres of the pylorus, which results in narrowing and sometimes almost complete obliteration of the lumen. The objective symptoms are, projectile vomiting, visible gastric peristalsis, constipation, diminished secretion of urine, and loss of weight. A tumour may be palpated in the right hypochondriac or epigastric regions. To accomplish this, considerable time and care are frequently required. Food or water should be offered to the infant during the procedure to produce relaxation of the abdominal

muscles. About 75 per cent of our cases occurred in male infants. The first symptoms of the disease usually appear during the second, third or fourth week of life. Only 11 per cent of our patients vomited at birth, while the maximum age at onset was seventy days. The treatment consists in immediate operation. This is followed by a simple transfusion. Post-operative treatment consists in raising the foot of the bed until the patient recovers from the anaesthetic. The infant is then turned on the right side and the head raised. Half an ounce of breast milk should be offered four hours after the operation, and the amount increased by a quarter of an ounce every four hours until the caloric requirements are fulfilled.

TETANY

Tetany is caused by a deficiency in the diet of the antirachitic substance, or vitamin D, which results in a reduction of the blood calcium. Convulsions are the predominant symptom. In certain cases they may occur as often as thirty or forty times a day. The next symptom, and one which is almost invariably overlooked, is a peculiar inspiratory crow produced when the child cries. Chvostek's sign, which is a contraction of the facial muscles elicited by tapping the side of the cheek, is almost invariably present in infants with tetany. It is due to a hyper-irritability of the facial muscles. This sign is of no significance in infants over two years of age. A characteristic position of the hand (carpopedal spasm) is present in a moderate percentage of cases. Sometimes this position of the hand may be produced by a constriction of the arm for one or two minutes, and when the spasm is produced in this manner it is called Trousseau's sign. The before-mentioned five symptoms of tetany, namely, convulsions, laryngospasm, Chvostek's sign, carpopedal spasm, and Trousseau's sign are all due to hyper-irritability of the neuro-muscular system.

The age incidence and seasonal incidence of tetany are singularly striking. Of the cases encountered in the hospital during the past five years 80 per cent occurred at the fifth, sixth, seventh, eighth and ninth months of age, and 85 per cent occurred in the months of January to May inclusive, the highest incidence being in March and April.

In regard to treatment the convulsions may be controlled by the administration of 15 to 25 c c of a sterile 8 per cent solution of magnesium

sulphate injected subcutaneously. As the convulsions are a result of the low calcium content of the blood, calcium chloride should be given. The amount should be 15 grains four or five times a day for the first two days, then the number of doses should be reduced to three a day. This should be continued for three weeks. The calcium chloride may be dissolved in a little water and placed in the feedings. Cod liver oil should be started, 1 drachm t.i.d., and continued for a long period. If possible the infants should be exposed to the direct rays of the sun.

SCURVY

Scurvy is caused by a deficiency in the diet of the anti-scorbutic substance called vitamin C. The symptoms of scurvy are pain on being handled, bleeding and swelling of the gums around the teeth, blood in the urine or stools, and swelling at the ends of the long bones. The swelling is due to a hæmorrhage under the periosteum. This at first glance may appear as a swelling of the joint which often leads to the mistaken diagnosis of arthritis of rheumatic origin. Enlargement of the costo-chondral junctions is also present, but this enlargement is more angular than that found in rickets. Seventy-five per cent of the cases encountered in this hospital occurred in infants from 8 to 12 months of age. It is rarely seen in those more than one and a half years of age, which is of considerable value in the differential diagnosis of scurvy and rheumatic arthritis as the latter condition is practically unknown under three years of age. The treatment consists in the prolonged administration of one half to one ounce of orange juice twice a day. This may be added drop by drop to the cold feeding. If diarrhoea is produced, twice the amount of canned tomato juice may be used. Every infant more than five months old should receive at least two drachms of orange juice a day as a prophylactic measure.

INTUSSUSCEPTION

Intussusception is an invagination of the bowel within itself. It usually starts at the ileo-cæcal valve. The outstanding symptom is sudden onset of pain in a previously healthy infant. The parent can generally remember the exact time of the onset of the symptoms. Vomiting begins, and, usually after the passage of one normal stool, the typical red currant jelly stool appears. This consists of mucus and blood. Rarely the stool may consist almost entirely of mucus with

only a little blood. Examination of the relaxed abdomen reveals a sausage-shaped tumour, usually lying transversely across the upper part. It is frequently necessary to give a little anæsthetic to produce relaxation. Rectal examination will disclose the typical stool, and if the condition has been present long enough the head of the intussusception may be felt. In a few hours shock-like symptoms appear, due to the absorption of toxins from the obstructed bowel. Sixty-five per cent of cases occur in infants from four to ten months old and only an occasional case in children over eighteen months of age. The treatment consists in the immediate reduction of the tumour by an abdominal operation. A delay of a few hours may be fatal. The prognosis depends upon the man who first sees the case.

ACUTE INTESTINAL INTOXICATION

Acute intestinal intoxication is a shock-like condition which results from the absorption of toxins from the gastro-intestinal tract. The toxin is probably of a split-protein nature. The intoxication is practically always preceded by diarrhoea. The outstanding symptom is progressive drowsiness, accompanied by vomiting. Pallor or cyanosis may result from the effect of the toxin on the circulation. The liver is usually enlarged. The treatment consists in the withdrawal of all food, and the oral, intravenous, and subcutaneous administration of glucose until the drowsiness has been absent for one or two days. Gradually increasing quantities of two per cent lactic acid milk may then be offered. If the drowsiness is marked a transfusion of blood is indicated. In very severe cases an exsanguination-transfusion is a life-saving procedure. The mortality even with the best of treatment is very high.

MONGOLIAN IDIOCY AND CRETINISM

These conditions of defective mental development are frequently not differentiated by the family physician. The vast majority of Mongolian idiots are referred with a diagnosis of cretinism. A survey of the records of this hospital show that Mongolian idiots are encountered more frequently, as during the past five years forty-three Mongolian idiots were admitted and only twelve cretins. The facies of the Mongolian idiot is quite characteristic. The eyes are almond-shaped, and slant downwards and inwards. The epicanthic fold is marked. These

characteristics become more evident when the child cries. The tongue usually protrudes, and only in this respect does the appearance of the Mongolian idiot resemble the cretin. In a number of cases the external ear is crinkled, due to maldevelopment of the cartilage. Congenital defect of the heart or palate is frequently present. The head tends to be flattened from before backwards. The hands are short and stubby, and the little finger is frequently curved inwards ("baseball finger"). Hypotonicity of the body is marked and the feet can readily be placed behind the head. These infants are subject to frequent head-colds, and usually die of a bronchopneumonia during the first two years of life. No treatment improves the condition.

Cretinism is the result of a congenital deficiency or absence of the thyroid secretion. The features are coarse. The skin is dry and doughy but does not pit on pressure. The nose is broad, the lips thick, and the jaw heavy. The tongue is large and protuberant. The whole face presents the appearance of having been pushed back, with the force applied at the bridge of the nose. The hair is coarse and wiry. The extremities are short. The temperature tends to be subnormal.

The administration of thyroid extract produces a marked improvement in from one to two months. This treatment has to be continued throughout life. The dosage at first is usually about one half a grain three times a day, which is not increased as long as the patient shows physical and mental improvement. If necessary as much as 10 to 15 grains may be given daily.

Evidences of over-dosage are, increased perspiration, pallor, prostration, and an abnormally high pulse rate. Although the physical development may become normal these patients are always mentally backward.

HEART MURMURS

Heart murmurs may be divided into three groups, congenital, functional, and acquired. The congenital heart murmur is present from birth. It is loudest over the base or body of the heart, and the intensity varies from the very faintest sound to the loud "machinery" type of murmur. The intensity of the murmur bears no relation to the severity of the lesion. Enlargement of the heart takes place to the right. Functional murmurs also occur over the body of the heart and are not transmitted. Although the exact cause is not known they are usually considered to be the result of changes in the

blood due to anæmia, or to dilatation of the heart as the result of some febrile condition. They are always of a very soft blowing systolic character and frequently disappear on exercise. Indeed, they tend to disappear spontaneously. Examinations over a long period may be necessary in order to make a definite diagnosis. Acquired heart murmurs differ considerably from the above mentioned conditions. A point of very great practical value in the differential diagnosis is that acquired heart disease is quite rare under four years of age. The character of the acquired heart murmur in children is the same as in adults. The murmurs most frequently encountered are systolic in time, heard best at the apex, and transmitted towards the axilla. Enlargement of the heart is toward the left. A history of sore throat, rheumatism, or chorea is usually obtained.

OTITIS MEDIA

Inflammation of the middle ear is a condition which is frequently overlooked. During the past five years no less than 2,094 cases were encountered in the medical service of this hospital. The frequency of this condition in infancy is due to the prevalence of upper respiratory infection, in conjunction with the short straight Eustachian tube of infancy which allows easy access of the infecting organism to the middle ear. The presence of otitis media should always be considered in any infant with an unexplained fever, as this may be the only symptom. Usually however the infant is irritable. As a result of the infection a gastrointestinal disturbance may develop. The infant practically never indicates the presence of pain in the ears. If the resistance of the patient is low, there may be little or no elevation of temperature. Otitis media is invariably secondary to a nasopharyngitis. Accordingly, the ears should always be watched carefully in any upper respiratory infection. Examination is most readily made by means of an electric auriscope. If the drum is reddened the condition may be treated by the administration of 1 to 2 drops of warm Keith's dressing in the ear every 4 hours. If bulging occurs, paracentesis is indicated, followed by dry wiping or syringing.

PYELITIS

Pyelitis is an infection of the pelvis of the kidney, which in severe cases extends into the kidney substance itself, producing a pyelonephritis. The symptoms are, a high widely fluctuating

temperature with a sudden onset, frequently preceded by a chill, and occasionally a convulsion. There are frequency of micturition and loss of appetite. A history of frequency is difficult to obtain in infancy. In severe cases the patient becomes quite toxic. The physical signs are usually negative, but occasionally large tender kidneys may be palpated. A definite diagnosis can only be made by a microscopical examination of an uncentrifuged specimen of urine. The urine may be collected in the male by strapping an ordinary test tube on the penis. With the female a female infant urinal, or an ordinary glass bird-seed container may be held against the vulva by the diaper. Examination of the urine shows the presence of a large number of pus cells. Occasionally, due to the blocking of a ureter, the pus cells appear intermittently. Therefore, it may be necessary to examine two or three specimens, before the pus is found.

The age and sex incidence of the disease is of interest. Eighty per cent of the cases encountered at this hospital occurred in females, and more than 50 per cent of the cases were infants from three to eighteen months of age. The disease is uncommon under three months. The treatment consists in the administration of sufficient potassium citrate to make the urine alkaline. This may require from 40 to 300 grains per day. The average case requires 15 grains to 25 grains dissolved in 2 drachms of water, and administered 5 times per day, at an interval of 4 hours. The urine must be kept alkaline for a period of about one year, otherwise the disease will recur.

AMMONIACAL DIAPER

The chief symptom of this condition is the presence of free ammonia in the wet diaper. Frequently, the ammonia is so strong that it "makes the eyes water" when the diapers are being changed. As a result of the local irritation produced by the ammonia there may be excoriation of the buttocks and genitalia, indeed, in many cases the infant is brought to the physician on this account. The condition is due to decomposition of the urea and ammonium salts in the urine with the resultant liberation of ammonia. The whole process takes place in the diaper after the urine is passed. Different theories have been advanced to explain this condition. Some authors believe it is due to the presence of certain bacteria in the diaper which act rapidly on the urea and the ammonium salts with the liberation of ammonia. Other writers consider

the ammonia the result of the action of traces strong soap left in the diapers. The question is not settled at the present time.

The treatment is very simple. One-third of a teaspoonful of baking soda (sodium bicarbonate) is given daily in each of three feedings. This results in the replacement of some of the ammonium salts in the urine by sodium salts. The amount of fat in the milk should be reduced, as this diminishes the amount of acids excreted in the urine. These acids frequently require ammonia to neutralize them. The diapers after being washed should be soaked for an hour or two in a saturated solution of boracic acid. They should then be thoroughly rinsed before use. This both sterilizes the diapers and removes any trace of soap. If these measures are carried out the odour of ammonia almost invariably disappears. The excoriated areas on the skin should be washed with olive oil, and then covered with cornstarch. Exposure of the parts to the air facilitates healing.

RETROPHARYNGEAL ABSCESS

This disease, which is not uncommon, is almost invariably overlooked, in spite of the fact that it can be readily diagnosed. During the past year 11 cases were admitted to this hospital, practically all of which occurred during the winter months. It is usually encountered in children less than two years of age. The condition is an acute inflammation of the retropharyngeal glands, which are situated on both sides of the midline posterior to the pharynx. It is always secondary to a nasopharyngitis. The prominent symptoms are noisy, snoring respirations with the mouth open, and retraction of the head. These symptoms are due to pressure on the larynx. An external swelling below the angle of the jaw is almost invariably present. The disease can only be diagnosed with certainty by palpation with the finger in the mouth. If no teeth are present a gag is unnecessary. A circumscribed mass can be felt on the posterior pharyngeal wall just lateral to the midline. Some cases of retropharyngeal adenitis do not go on to abscess formation. When definite fluctuation is present, the mass should be incised. The use of either an anæsthetic or an external incision is positively contraindicated. The patient, pinned in a blanket, is laid on the back with the head extending over the edge of the table. A mouth gag is inserted. It is essential that the knife used be wrapped with adhesive

so that only the terminal eighth of an inch of the blade is left unguarded to penetrate the tissues. Guided by the left index finger, a transverse incision is made across the most fluctuant portion of the mass. The knife is withdrawn and the index finger rapidly inserted in the opening and any adhesions broken down. The child is immediately turned on its face to allow escape of the pus. The procedure as outlined must be carried out rapidly, in order to prevent the aspiration of pus. Convalescence is rapid.

EXANTHEM SUBITUM OR ROSEOLA INFANTUM

This disease occurs usually in infants less than eighteen months of age. The onset is abrupt, beginning with a high fever of a fluctuating nature which persists three to four days. Usually on the fourth day, the temperature falls by crisis, and there appears a pink maculo-papular rash which persists for one to three days. As the rash fades there frequently appears a fine branny desquamation. The disease is contagious and there is complete absence of complications or sequelæ.

Exanthem subitum occurs most frequently in the late summer and early autumn, and during the winter months. The fever ranges from 101° to 105°, with a tendency to morning remissions.

The patient, in spite of the high fever, is usually carefree and happy which is of considerable diagnostic importance. The catarrhal symptoms of measles are absent. There may be slight congestion of the throat, conjunctiva, and buccal mucous membranes. Usually on the second or third day of the febrile period there occurs a general glandular enlargement, though often only the cervical and posterior auricular glands are involved. In many cases the enlargement of these glands persists for weeks. On the third to fifth day of the disease the fever falls by crisis, and usually coincident with this the rash appears, at first on the trunk, then spreading to the neck, face, posterior auricular regions, and the proximal half of the extremities. It is a bright pink or rose coloured maculo-papular rash. The maculo-papules in some cases coalesce, which may make the rash almost indistinguishable from that of measles. The spots disappear on pressure. After one to three days, the rash fades, frequently leaving a fine branny desquamation. A characteristic blood change is the presence of a leucopenia, with 70 to 85 per cent of lymphocytes.

There is no other exanthem in which the eruption is consistently coincident with defervescence, and with the disappearance of all signs of illness.

SPONTANEOUS CEREBRAL HÆMORRHAGE*

By F. H. MACKAY, M.D.,

Montreal

THAT the title of this paper may possess the flavour of the uninteresting and commonplace is freely admitted. That many of us here to-day may entertain the idea that in the study of brain hæmorrhage little remains to stimulate our imagination or arouse our interest is further admitted. And yet it is only within the last very few years that spontaneous cerebral hæmorrhage has attracted anything like the attention that it deserves. Because of this awakening interest, and the mental ataxia which attended my own earlier recognition of the condition, I have ventured to bring it up for our consideration.

I trust that I am casting no undue aspersion upon our profession when I suggest that the term itself awakens only but one very definite mental picture in the mind of the average physician. He conjures up the figure of an oldish person, with well-advanced arteriosclerosis, lying in a comatose or semi-comatose state, completely hemiplegic, and awaiting only the final flicker of the flame of life.

It is not, however, of this clear-cut picture of intra-cerebral hæmorrhage, which I am sure we all recognize at a glance, that I propose to speak. Rather do I wish to attract your attention to a vast series of sudden hæmorrhagic disorders, occurring in or upon the brain, at all ages, and under unrecognized pathological conditions. If,

* Read at the meeting of the British Columbia Medical Association at Victoria, June 12, 1928.

on the one hand, we eliminate from our consideration definitely intracerebral hæmorrhage due to vascular disease, and, on the other, such clear cut and well-recognized conditions as subdural hæmorrhage of traumatic origin, we still encounter a miscellany of hæmorrhagic conditions none the less numerous and vastly more interesting.

First in importance among these should be placed subarachnoid hæmorrhage, a term recently added to our nomenclature to denote sudden spontaneous hæmorrhage between the arachnoid and the brain surface. The onset is characteristic, probably more so than in any other type of cerebral hæmorrhage. The patient, while in the full enjoyment of his usual good health, is suddenly stunned. He has the sensation of being struck on the head as if from behind. Intense headache supervenes, and he rapidly but steadily passes into unconsciousness. Gradually the breathing becomes stertorous, the pulse slowed, and the pupils dilated, indicating the gradual development of cerebral compression. In contradistinction, however, to intracerebral hæmorrhage, we find few, if any, localizing signs. Rather is there a general paresis with bilateral manifestations. In the severer types, the patient is quite unconscious, breathing is stertorous, the pulse slowed, the pupils dilated, sometimes unequal and occasionally inactive to light. Muscular tone is at first increased, but gradually, in the course of a few hours, passes through hypotonia to complete flaccidity. Reflex activity is increased throughout and accompanied by such pathological reflexes as the Babinski, Oppenheim, or Chaddock phenomena, ankle or patellar clonus, and even absence of the abdominal reflexes. Commonly, these pathological signs are equally manifest on both sides, though occasionally they evidence a preponderance of pressure on one or other side. Never, however, does one see complete hemiplegia, as in intracerebral hæmorrhage.

A quite different picture may be observed in the less severe cases. Often one sees here evidence of meningeal or cranial nerve irritation, accompanied by restlessness, irritability and mental confusion rather than the well-marked coma of the more severe cases. Cervical pain, with retraction of the head and a more or less well-marked Kernig sign, further complicate the picture, and are frequently re-

sponsible for the diagnosis of meningitis, until the spinal fluid examination renders this diagnosis untenable. In both types, however, the onset is similar. A sudden attack of pain, as if something had snapped in the head, and gradually developing weakness characterize both. The diagnosis of subarachnoid hæmorrhage, while inferred from the clinical history and findings, must depend, finally, upon the examination of the spinal fluid.

A not uncommon clinical finding in these cases is that of massive albuminuria, or glycosuria, which naturally enough suggests to the physician's attention either uræmia, in the first case, or diabetic coma in the second. The hæmorrhage in these cases is essentially irritative and, as might be expected, settles on or about those basal structures irritation of which is known to set up glycosuria or albuminuria. The transitory nature of these findings, the blood chemistry and, finally, the spinal fluid findings, suffice to eliminate the possibility of either condition in the genesis of coma of this type. While the level of nitrogen retention is frequently raised above normal, it is never comparable to that of true uræmia.

Whether, however, one is dealing with the severe comatose type or the irritative meningeal type, the diagnosis must ultimately rest upon the examination of the spinal fluid. This examination should not be undertaken without first noting the actual pressure in the spinal canal, for which the use of the manometer is essential. So high is the pressure reading in most of these cases that the ordinary mercury manometer is quite inadequate. Normally, this apparatus registers from 8 to 12 mm of Hg, while under pathological conditions the readings may be as high as 60 mm. In the cases under discussion, the readings ranged from 25 mm to 55 mm, all being materially elevated but, as would be expected, registering the higher levels in the severe comatose type of case. Just one word in passing on the commonly employed practice of estimating spinal pressure by the drop method. Fundamentally, it is unsound and, practically, it is misleading and worse than useless.

In the first few days, blood is always present and is uniformly distributed throughout the fluid. It does not clot after standing, as may be the case if due to needle trauma. After the

first few days, the blood tends to disappear, but continues to disclose itself in the appearance of xanthochromia, the yellowish fluid which indicates a previous hæmorrhage. The rapidity of this disappearance of blood cells is rather remarkable, and the passage from frank blood to xanthochromatic fluid is marked by certain cytological phases which, if not understood, may be responsible for serious diagnostic error. Following the fragmentation and final dissolution of the red corpuscles, leucocytes and lymphocytes appear in great numbers, constituting, no doubt, the phagocytic agents by which this dissolution is brought about. This leucocytic phase, if unappreciated, tends to confuse the picture and presents further confirmation of the diagnosis of meningitis.

The spinal fluid, then, presents various consecutive phases which, if properly understood, establish unassailable evidence of hæmorrhage. The successive stages of uniformly blood-stained fluid under pressure giving place to xanthochromia, of leucocytic passing to lymphocytic invasion, and, finally, to clear fluid, give us our *sine qua non* of subarachnoid hæmorrhage.

The first type of case may be illustrated with the following histories.

CASE 1

F. C., 52 years old, a heavily built, plethoric engineer, was admitted to the Montreal General Hospital in September, 1927, a few hours after a sudden attack of pain in the head. He believed he was struck on the head with a hammer. His past history was uneventful always a hard worker, smoked moderately, took an occasional drink, denied venereal disease. In the course of one hour he became fully unconscious, and five hours later was examined in the ward. His breathing was stertorous, pulse 68-70, temperature $101\frac{1}{4}^{\circ}$ F. The general muscular condition was one of hypotonia, with intermittent, spasmodic contractions of the right arm, no localized paresis. The pupils were dilated, regular, sluggishly reactive to light. The eyes were fixed in mid position. The eye grounds were normal.

All the deep reflexes were hyperactive and intensified on the left side. Bilateral Babinski and Chaddock phenomena were noted, and there was a well sustained ankle clonus on the left side. Abdominal reflexes were doubtfully present. Tendon jerks of the upper extremities were present throughout, but intensified on the left side. A crude sensation to pain was noted to be present on both sides, inasmuch as there was with drawal response to prick. Kernig's sign was not elicited.

Spinal Fluid—Pressure with the mercury manometer was 38 mm (normal 8-10), the fluid was uniformly blood stained, but showed no clot on standing. The Wassermann test was negative.

Blood—Red blood cells, 490,000 per c.mm. No abnormal red cells were seen, hæmoglobin 85 per cent (Dare), white blood cells, 12,400. The relative proportion of white cell elements were maintained. Urea

nitrogen was 17 mgm. per 100 c.c. The Wassermann test was negative.

Urine was clear, sp. gr. 1018, reaction, acid, albumin ++, sugar + (Fehling's), no casts or red cells.

X-ray examination of skull revealed no abnormality. Cardiovascular System was normal, blood pressure, 138/85.

The spinal pressure was gradually reduced daily until 14 mm. Hg was registered, and in the course of eight days the patient passed from the unconscious state to one of delirium and disorientation for place and time, from this to mild confusion and, ultimately to his normal mental state. Along with this general improvement, his normal muscular tone became re-established and all reflex activity took on its normal expression. At the end of the fourth day, the temperature curve became normal and remained so. Six days following the initial puncture no red cells could be found in the spinal fluid, but numbers of leucocytes and lymphocytes were in evidence, while a distinct yellowish colour preceded the clear fluid observed during his last days in the hospital. All evidence of albuminuria disappeared four days after admission. Two weeks after discharge, or eight weeks after the initial hæmorrhage, he resumed work as engineer on a fast passenger train and has remained on full duty since.

CASE 2

The second case is that of a woman, aged 35, whom I saw in consultation with Dr. Ilievitz, and was kindly permitted to follow throughout her illness.

Suddenly, on the morning of March 20, 1927, while talking to her family, she was taken with severe pain in the right side of her head. She clapped her hand to her right forehead and clutched at her hair, gradually sinking into semi-unconsciousness, in which state she was admitted to the hospital, two hours after onset of pain. During this period, she vomited several times and spasmodic contractions of the left arm and forearm were noted. Her past history revealed nothing of significance.

On admission, she was obviously in pain, tearing her hair, clutching at her head and making such an uproar that hysteria was suggested by one physician who saw her. The temperature was 100.2° , pulse, 62, respirations, 20. She remained conscious throughout her illness, though for several hours she was stuporose and confused, being aroused to the conscious state with considerable difficulty. The pupils were dilated and unequal, the right being the larger, and both reacted to light sluggishly, no nystagmus, no ocular paresis. The eye grounds were normal on admission, but, three days later, showed moderate bilateral papilloedema, and in the periphery of the left retina numerous petechial hæmorrhages in the superficial layers (Dr. Rosebaum). Ten days later, the swelling and hæmorrhage had disappeared, and a left-sided homonymous hemianopsia was discovered. No paresis of the face, arms or legs could be made out, but muscle tone was definitely increased on both sides and particularly so in the left arm and leg. Infrequent spasmodic contractions of the left arm continued for several days. Sensation of all forms showed no demonstrable impairment. All tendon jerks were exaggerated, the knee and ankle jerks on the left side being definitely hyperactive. Both plantars were extensor in type, and there was a well sustained ankle clonus on the left. The abdominals could not be elicited. Kernig's sign was present on both sides, and there was well marked retraction of the head.

Spinal Fluid—The spinal fluid was uniformly blood stained, did not clot on standing and was under a pressure of 35 mm. Hg. This was daily reduced by repeated lumbar punctures until 12-15 mm. Hg was recorded. The centrifugized specimen showed a faint, yellowish tinge to the supernatant fluid which, as the red cells disappeared, gradually deepened to a definitely xanthochromasia. Leucocytes and lymphocytes were

abundantly present after the sixth day. On discharge, May 2nd, the spinal fluid was normal, with the exception of a persistent positive Pandy reaction for globulin. Wassermann reaction in blood and spinal fluid was negative.

Blood Chemistry—The blood sugar was 0.186 per cent, creatinine, 1.2 mgm per 100 c.c.

Urine—Clear, sp. gr. 1022, acid, albumen +, sugar, qualitatively present to Fehling's test. Both sugar and albumen disappeared from the urine before she left the hospital. The cardiovascular system was normal, blood pressure 120/85.

This patient made a complete recovery, and resumed her household duties five weeks after the onset of her illness. Clinically, the earlier findings in this case closely simulated meningitis. The severe headache, the slight temperature curve, the head retraction, and the Kernig sign were given their proper significance only after the spinal fluid findings were revealed.

These two cases have been selected from five of a similar nature, as clinical illustrations of that very definite entity amongst brain hæmorrhages in general, spontaneous subarachnoid hæmorrhage.

DISCUSSION

Anatomically, bleeding into the subarachnoid space may occur in one of several ways: (1) directly from one of the larger vessels lying in the space itself, (2) from extension of an intracerebral hæmorrhage, either into the subarachnoid space itself or, if more deeply placed, into one of the ventricles, (3) as a result of trauma, in which case both subdural and subarachnoid spaces may be inundated. By the term spontaneous subarachnoid hæmorrhage we refer only to those cases which are included in the first type.

I am convinced that many of the cases of type 2 are etiologically and pathologically identical with those of type 1, but inasmuch as they are marked by evidence of brain tissue destruction, from which complete recovery seldom if ever takes place, most authorities on this subject exclude them from the picture of spontaneous subarachnoid hæmorrhage. Later, however, some interesting examples of this class will be referred to. Obviously, type 3 cases of traumatic origin, have no place in this discussion.

Most cases of spontaneous subarachnoid hæmorrhage may be classed under one or other of two groups, which, after all, merely represent degrees of severity in the same clinical process. In those cases of lesser severity, as illustrated in Case 2, the predominant feature is one of meningeal irritation. The initial headache persists, and is followed by head retraction and the

Kernig phenomenon. There is partial retention of consciousness throughout or, at most, only a temporary loss of consciousness, associated with the initial shock. The mental state is often one of confusion and disorientation, while Korsakoff's syndrome has been reported by some authors. The severer cases, on the other hand, present, rather, the picture of cerebral compression, with early developing and persistent coma, dystonia and increased reflex activity. These constitute the apoplectic type, and, indeed, the differentiation from intracerebral hæmorrhage is not always easy. It may be only after recovery has taken place that the absence of evidence of brain tissue destruction, with complete disappearance of all signs, establishes the differential diagnosis.

Between these two extremes lie cases of varying degrees of severity, exhibiting features of one or other type or, as may be the case, of both. Not infrequently, the apoplectic type assumes the meningeal syndrome during the process of recovery. Common to both types are those characteristic features upon which one must rely for diagnosis of the condition: (1) the sudden onset, often in apparently healthy individuals, with severe pain and the sensation of "something having snapped in the head", (2) the rapid development of signs of cerebral compression or meningeal irritation, according to the severity of the rupture and rapidity of the bleeding, (3) usually a mild elevation of temperature with a moderate slowed pulse, (4) the development in some cases of papilloedema and hæmorrhagic retinitis, (5) the development, in some cases, of glycosuria and massive albuminuria, (6) finally, and essentially, the characteristic spinal fluid findings.

DIFFERENTIAL DIAGNOSIS

In recent years, the great clearing house of neuropsychiatric difficulties in diagnosis has been encephalitis lethargica, and it is not in the least surprising that many of these sudden hæmorrhagic disasters should have been placed in this category. The somnolence, with signs of meningeal irritation, and the mild elevation of temperature, frequently indicate inflammatory disease with encephalitis lethargica or meningitis in the foreground. Both these diseases, however, are readily excluded by the examination of the spinal fluid. The not infrequent finding

of sugar or albumen in large quantities in the urine may direct the physician's attention to diabetic coma or uræmia but here again the state of the spinal fluid and the estimation of nitrogen retention in the blood suffice to throw these two conditions out of court.

More difficult of interpretation are those cases in which the blood in the subarachnoid space has arisen from the rupture of an intracerebral hæmorrhage, either directly into the subarachnoid space or indirectly by way of the ventricles. It may be quite impossible in some cases to satisfy one's self that these possibilities are excluded, but the presence of evidence of brain tissue destruction, such as a frank hemiplegia or aphasia point to the cortex or sub-cortex as the site of the primary rupture.

The onset, course and termination of some of these intracerebral hæmorrhages are so similar to those under discussion that there appears little justification for their exclusion from the clinical picture of spontaneous subarachnoid hæmorrhage. In the present state of our knowledge—or rather, lack of knowledge—of the pathology of spontaneous hæmorrhage in young and apparently healthy persons, it would appear that the question of type—intracerebral or extracerebral—is an accidental one depending upon the site of the initial lesion. In elucidation of my contention in this matter, I will outline two cases which but for the site of the initial ictus must have been readily classed as cases of spontaneous subarachnoid hæmorrhage.

CASE 3

A healthy boy, of 13 years, seen in consultation with Dr Harry Shaw. His previous history was devoid of any untoward happening and he was regarded as exemplary physically, mentally and morally. Shortly after going to bed on November 1, 1926 he was suddenly seized with intense headache vomited several times and quickly passed into coma. This coma wore off and when seen in the early morning he was conscious—suffering pain intensely irritable and throwing himself about the bed. The pulse was 48, temperature 99.2° respirations 24. Pupils were equal regular and showed a normal reaction to light. The fundi of both eyes showed no apparent abnormality, no nystagmus. No ocular, facial or limb paresis. The neck muscles were rigid, with well marked retraction of the head and there was a strongly positive Kernig's sign on both sides. The deep reflexes could not be elicited and the plantars were normally flexor in type. The abdominals were present and equal on both sides.

The impression was that the case was one of cerebro spinal meningitis.

Spinal Fluid—This was under pressure of 25 mm Hg, and was deeply and uniformly blood stained. The supernatant fluid showed a definite yellowish tinge, which gradually deepened from day to day into xanthochromia. An increase in the white cell elements

was noted on the first examination and later the lymphocytic variety especially became very numerous, as the red cells tended to disappear. Cultures of the fluid remained sterile.

Rapid and satisfactory recovery was made from this initial hæmorrhage so that by November 16th he was apparently quite well. No pain or headache, no objective signs of cerebro-spinal injury. The spinal fluid contained no red cells but was markedly xanthochromic. He was eating, sleeping and acting normally.

On November 18th he was again seized with headache vomiting and in a very few minutes coma. There was violent spasmodic twitching of the right arm and leg while the left arm and leg were in a state of flaccid paresis. The head was held rigidly towards the left and the eyes turned towards the right. The pupils were equal dilated and reacted to light. Deep reflexes were exaggerated but equal. Bilateral Babinski and Chaddock phenomena were present with bilateral ankle clonus. Abdominals were absent on both sides.

Examination by Dr MacMillan showed bilateral hæmorrhagic retinitis with many small hæmorrhages into the periphery of both retinæ suggestive sweating of the temporal side of right disk. There was paresis of the external rectus on the left side.

Spinal Fluid showed pressure 30 mm Hg and was deeply blood stained. No clot on standing.

Again improvement set in and once more he returned to normal activity. During this phase of normality Dr Waugh made a complete examination of his blood which he summarized as follows: 'There is nothing in the blood picture to suggest blood disease as the cause of the cerebral condition. No hæmorrhagic diathesis. The pathological features are the high viscosity and concentration of the blood producing anhydramia. This is probably due to fluid depletion. The relatively high bilirubin content speaks against any extensive hæmorrhagic extravasation.'

On November 28th the spinal fluid was deeply coloured with a high white cell count. On November 30th he had a sudden seizure for the third time with headache coma and flaccid paralysis on both sides and with bilateral Babinski and ankle clonus and absent abdominal reflexes.

After lumbar puncture which again showed bloody fluid, he regained consciousness for several hours but gradually sank back into unconsciousness with a pulse of 34 and Cheyne Stokes respiration. He died on December 2nd.

Autopsy Findings—The brain only was examined. Dr Connor reported as follows. The brain is large. The convolutions are flattened and the whole is covered with recent blood. A mass of blood has broken through the anterior part of the left lateral ventricle. On section a large hæmorrhage is present in the cortex of the left hemisphere. All the ventricles are filled with blood as far back as and excluding the 4th ventricle. The original hæmorrhage appears to have been in the cortex outside the ventricle and to have broken through to the subarachnoid space and into the left lateral ventricle. After washing away the blood an exhaustive examination of the vessels failed to reveal the presence of aneurysm or rupture in the wall or one of the larger vessels.

'Numerous sections from various portions of the brain were examined microscopically. These in general show cerebral cortex or portions of basal ganglia with hæmorrhage. In no section is there any line of demarcation between hæmorrhage and brain substance. The immediately surrounding tissue is made up of degenerating nerve and glial cells in which there are many phagocytic cells containing blood pigment. There is a condensation of neuroglial cells in places but there is no evidence here of a neuroglial tumour. No mitotic figures are found, no separation from the more normal tissue can be demonstrated and the contiguous

blood vessels do not show the endothelial proliferation common in the vicinity of neuroglial tumours

"The few nerve cells observed are somewhat swollen and show with phosphotungstic acid hæmatoxylin stain a few Niels granules indicative of degeneration. There seem to be more satellite cells around them than usual. The hæmorrhage, in bulk, is rather recent, but evidence of old hæmorrhage is present in the numerous pigmented endothelial cells around the blood. In this area, in addition to the pigmented cells, there are many large, swollen, vacuolated cells, commonly known as *gitterzellen*.

"No defect of blood vessels can be found. Those large enough to have muscular and elastic tissue walls show no change from the normal. The smaller ones are dilated in the region of the hæmorrhage, but an actual rupture cannot be demonstrated."

CASE 4

A young man, 31 years old, whose health was always excellent. There was no record of any previous disease or ill health and, with the exception of strong addiction to alcohol, his past history was free from comment.

On December 7, 1927, he was admitted to the Montreal General Hospital unconscious and hemiplegic, with the report that he had been perfectly well when he had retired at 11 o'clock the previous night. In the morning, his wife found him in an unconscious state and unable to move his right arm or leg. On admission he was deeply somnolent, but could be aroused to apparent consciousness. He could not speak, however, and gave little sign of recognition of his surroundings. The temperature was 100.3°, pulse, 60-64, respirations, 18-20. The pupils were equal, small, slightly irregular, and did not respond to light. There was complete right-sided hemiplegia involving face (lower), arm, and leg. He could mumble a few, indistinct and unrecognizable sounds. The eye fundi were normal on admission. All deep tendon reflexes were greatly exaggerated on the right side, while positive Babinski, Chaddock, Oppenheim, and Hoffman reflexes were obtained on the right side. Ankle clonus and absence of the abdominal reflexes were noted on the right side. All reflex activity on the left side was normal. The cardiovascular system was normal. The blood pressure was 140/100, on discharge, 120/80. The radial arteries were soft and easily compressible.

Urine—Acid, sp. gr. 1022, albumin + + +, sugar, negative to Fehling's, no casts or red blood cells were seen.

Spinal Fluid—Pressure, 50 mm Hg. The fluid was deeply and uniformly bloody. The pressure was gradually reduced to 25 mm Hg, with marked improvement in his mental state. Repeated daily lumbar punctures, over a period of ten days, reduced the pressure to 15 mm Hg.

The spinal fluid in this case was typically that of subarachnoid hæmorrhage, and passed through the stages of red cell absorption, xanthochromia, leucocytic and lymphocytic invasion to clear fluid with excess of globulin.

Ten days after admission, the optic discs began to show blurring with venous congestion, and on February 3rd Dr. Mathewson reported "Definite optic neuritis in both eyes with a few superficial retinal hæmorrhages."

Before discharge on March 1st, all signs of diseased fundi had disappeared. The blood and spinal fluid Wassermann tests were, on several occasions, negative. A mild luetic curve in the colloidal gold was accounted for by the presence of blood pigments. The nitrogen retention and blood sugar curves were found to be within normal limits.

After reduction of the spinal pressure to lower limits consistent with life, his mental confusion and somnolence completely cleared up and definite improvement took place in his speech. While still showing defect in the receptive speech mechanism, emissive

speech was almost normal. The hemiplegia disappeared, so far as movement indicated, but evidence of pyramidal tract involvement on the right side was still present in the persistence of the Babinski, Chaddock, and Oppenheim phenomena, and the absence of the abdominals on the right side. In addition, a decided limp and hyper-tonia of the right arm marked the irreparable damage to the pyramidal system. The pupils, which on admission were small, slightly irregular, and inactive to light, resumed normal size and activity with the return of normal intraspinal pressure.

In Cases 3 and 4, we have definite evidence of brain tissue destruction, in Case 3 in the autopsy findings, and in Case 4 in the no less reliable evidence of persistent pyramidal impairment and aphasia, which could be due only to a destructive lesion in the left cerebrum.

While anatomically they cannot be classed as subarachnoid, yet in the suddenness of onset, the spontaneity, the incidence in young and heretofore healthy persons, in whom no evidence of cardiac, vascular or blood disease could be discovered on repeated examinations, and finally, in the failure to discover any break in the continuity of the cerebral vessels in Case 3, we are forced to admit their clinical identity with Cases 1 and 2, which have been selected as types of spontaneous subarachnoid hæmorrhage.

PATHOGENESIS

This brings us to a consideration of the pathological changes underlying this condition. I wish to say at the outset that I have had to deal with only a very limited number of cases—8 in all—of which two died, but in neither of these did exhaustive examination of the cerebral vessels reveal the cause of the hæmorrhage. A review of the literature, however, indicates a number of causes, chief among which are the causes of cerebral hæmorrhage in general, *viz*, arterio-sclerosis, bacterial infection, toxic degenerative processes, notably chronic alcoholism and syphilis. With these known causes of brain hæmorrhage, whether of the intracerebral or the subarachnoid type, we are not concerned in this discussion. Only cases which have occurred spontaneously in the absence of any known arterial, renal or blood disease, have been considered as lying within the purview of this paper. In only one of the four cases cited was there any suggestion, from either the past history or clinical examination, of the cause, and that was in Case 4, which, though that of a young man, reported immoderate addiction to alcohol for several years. Probably, the best explana-

of his neck, to be very restless, extremely ugly and unlike himself. So unlike himself was he that his mother stated that when he was sick before he would do every thing she wanted pleasantly.

At this time examination showed the reflexes to be active, the pupils equal, reacting to light and accommodation, the abdomen scaphoid, and slight rigidity of the recti. The following negative facts are of interest. He had neither photophobia, Kernig's sign, tache cérébrale, retraction of the head, nor changes in the ears, throat and fundi. For a week he screamed almost steadily with the pain in the back of his neck. His skin became hypersensitive, and his muscles would twitch when touched. Kernig's sign was now present. His fever varied from 97°-104°F in a most irregular manner, heart rate, 60-90, the rhythm was irregular and the sounds of fair quality. Involuntary urination, slight albuminuria, and constipation were present. No photophobia. A lumbar puncture was done, and 15 c.c. of fluid removed, with very slight increase of pressure. The fluid was clear, eleven lymphocytes, glucose present, no globulin, no filmy clot on standing, the smear was negative for tubercle bacilli. For one week following the puncture he was less restless, the skin was less sensitive, and there was no fever. The boy only screamed occasionally and seemed better. Drowsiness then began to appear, with photophobia of the left eye. The left fundus showed engorged veins and a hazy nasal margin. Temperature was 106° F. For two weeks he became increasingly drowsy, with periods of extreme restlessness and screaming. The screaming became more frequent. The tendency to drowsiness in the daytime and restlessness at night was marked. He was very "ugly," the fever irregular, the heart action slow and irregular, urination involuntary and painful, the skin was sensitive, and the neck painful. Another lumbar puncture showed a clear fluid, with fourteen lymphocytes, glucose present, no globulin, the smear was negative for tubercle bacilli.

The boy was brighter following the puncture, stopped screaming, and was less restless, but would not answer questions. The following day he became drowsy and for a week slept most of the time. When awake he appeared bright, would look at picture books, but would not talk. The photophobia was gone and the ocular fundi appeared normal again. His condition remained unchanged for about two weeks. Then he would steal out of bed to look out of the window, but still he would not talk. About ten days later he began to say "yes" to everything, but could not be made to speak another word. He would draw pictures, climb over the top of the bed, and would attempt to get to the top of everything in the room. He would obey when spoken to.

The following incident will give some idea of his mental condition at this time. I asked him to write his name and he wrote "Donal Simmmml." His expression was that of a person confused. I did not correct him, but repeated the question on several days, and he wrote always as above. Finally, I wrote his name correctly and he copied my spelling. At the places of his former mistakes he would smile, and appeared quite pleased to have overcome his difficulties. For the next few weeks he was taught a large number of monosyllabic words, and was taught to use them intelligently. Later, a few simple mental problems were given which he learned to answer. He was very slow of thought.

About the last of August, almost five months after the onset of the disease, he began to have a slight stoop forward and a somewhat expressionless face. He developed some bad habits. He would run away from home and drive on delivery teams, pull the cat's tail, was disobedient and had a very disagreeable manner. He was mentally sluggish, would not touch the piano, and would not concentrate upon anything for any period of time. There was an absence of personality.

To day the boy shows much the same stoop, much the same facial expression as he did five months after the onset of his illness. No other characteristics of Parkinson-like syndrome have developed. Through careful home training and education at school, starting with blocks and paper objects, etc., the boy's mental condition has improved so much that he has returned to the regular school

grades to carry on his work. He is with children much younger than himself, but still is slow of thought and has become once more an obedient boy.

This patient illustrates the psychotic type of encephalitis lethargica. There was an onset of an infection resembling an intestinal disorder, subsequent eye symptoms and drowsiness, preceded by extreme restlessness, and followed by mental changes. A boy of excellent habits becomes a bad boy, develops slowness of thought, speech changes, and aphasia.

The difficulty in diagnosis is quite apparent. In children recovery is not as common as in adults, many of these children becoming a care to the State.

The next history is one which emphasizes the lethargic form of the disease and the type from which, no doubt, the misnomer "sleeping sickness" was derived.

CASE 3

A McC, aged 25 years, a lineman, took ill in August, 1925, with slight fever, constipation and restlessness. These symptoms lasted for a brief period, when he became drowsy and developed diplopia. The drowsiness and diplopia passed off in a few weeks and he returned to his work. For the next few months he appeared to be his former self. In February, 1926, six months after the onset of his disease, he began to have sleepy spells in the daytime. These became so marked that he would fall asleep while working on the pole as a lineman. His foreman became frightened that he would fall and gave him work on the ground. He would sit and sleep all the time, except when aroused by his fellow workmen. A nervous twitching of his muscles appeared about the same time. Examination at this time showed a marked inequality of pupils, which reacted to light and accommodation, some ptosis of both eyelids, slight spasticity of all his muscles, and some change in his facial expression. No tremor was present and his appearance was not that of the Parkinsonian type. The blood Wassermann was negative. The heart, lungs and abdominal viscera showed no abnormalities. For months he would sleep in the daytime, unless aroused, but was not so sleepy at night. His eyes remained unchanged. This patient was classified as a lethargic or somnolent-ophthalmoplegic type.

The types illustrated by the three foregoing histories have progressed and resulted in disabilities. Milder grades of the disease have been seen which did not result in severe disabilities. These milder forms may result in slight permanent speech defects or in slight permanent palsies. The following history illustrates this type of case.

CASE 4

J. R. S., aged 40 years, a janitor, took sick on April 18, 1924, with "la grippe" or "influenza." For one week he ran an influenzal course, and then he began to talk at random, to be very stupid, and to complain of pains in his muscles. He was very restless at night, talking wildly, but showing no signs of violence. For two days he had diplopia and a temperature of 99°-102°F, irregular in type. The wild talking continued for twelve days, and then he became very drowsy and stupid. There was no fever. Throughout this period he had fine irregular twitchings of his muscles. In another week he became brighter, the twitchings were gone, but the diplopia re-

turned. The right pupil became larger than the left, both pupils reacted to light and accommodation, muscle spasticity was very slight. Two weeks later the diplopia disappeared, but the large pupil remained. From this time on he gradually became stronger and returned to his former work. To day he shows only a slight monotony in his speech, the right pupil larger than the left, a slightly altered facial expression, and some slowness of thought. He works hard, does his work well, and, to the casual observer, he is his former self.

A number of very mild cases must be seen and pass unrecognized, owing to the difficulty of diagnosis in the early stages.

A type which unfortunately I have not seen in practice in New Brunswick is the "hyperkinetic." This has the main characteristics of the former types, but also has the severe symptoms of choreic movements or myoclonic contractions. The choreic movements may be irregular or regular, the regular, as in an extremity contracting 18-20 times a minute, or as twitchings in the abdominal muscles. The myoclonic variety may show parts of muscles contracting irregularly, due to an irritative lesion of the spinal cord. This type may go on to recovery, or may result in severe permanent disabilities. The fulminating form of this type, with death in a few hours, I have not seen in New Brunswick.

In a patient whom I saw outside of the province the choreic movements were bizarre, the restlessness extreme, the diaphragm contracting irregularly, with very difficult and irregular respiration. Death occurred in a few hours.

TREATMENT

The treatment of encephalitis lethargica is symptomatic, no specific remedy having been

found. The restlessness is improved greatly by lumbar puncture. Spasticity may be lessened by hyoscine, but will return unaltered after the drug has been discontinued. Hexamine is a useful drug and has been used in large doses in my cases. Potassium iodide and salicylates have been tried. Rest, skilful nursing, and re-education are valuable.

COMMENTS

A review of these histories shows that a patient taking sick with "influenzal" symptoms, who in a few days becomes restless, with slight fever, and develops transient eye symptoms and persistent drowsiness, should be suspected of being ill with encephalitis lethargica. This diagnosis can be confirmed by the presence of spasticity of the muscles, painful muscular contractions, irregular involuntary twitchings, ptosis, or irregularity of pupils and by lumbar puncture. Lumbar puncture shows a clear fluid, with a very slight amount of globulin, or none at all, with increased glucose content, 10-50 lymphocytes, giving a negative Wassermann and negative for tubercle bacilli. Very often the progress of the disease must be watched in order to establish the diagnosis by the development of the Parkinsonian syndrome, or the alteration of the mental condition. Lastly, the inability to diagnose any other condition is important.

Encephalitis lethargica is more prevalent in New Brunswick than is usually thought, and it is hoped that this paper will be a means of help to the general practitioner in his efforts to recognize this disease.

New Sources of Broad Tapeworm Infestations
Report of Fourteenth Native Case—Specimens of wall eyes and pickerel have been examined from most of the commercially important Canadian lakes, and in every case plerocercoids, which Teunis Vergeer has identified as *D. latum* have been found. Ten of these plerocercoids were taken from nine fish during the examination of a lot of forty one wall eyes, *Stizostedion vitreum* Mitch., sent to him from Lesser Slave Lake. Three plerocercoids of the same species were found in three of twenty five wall eyes from Lake Manitoba. One plerocercoid of the same species was found in a single fish in the examination of a lot of twenty three wall eyes from Lac la Biche (Alberta) and one plerocercoid was found in one of fifteen pickerel, *Esox lucius* L., from Lake of the Woods. Fish from Lake Winnipegosis can not be obtained at present because of legal restrictions, but this body of water is directly connected with Lake Manitoba and fish are able to move from one lake into

the other, making it highly probable that some fish in that lake also are infested with plerocercoids of *D. latum*. All plerocercoids have been fed to dogs free from *Diphyllbothrium*. Young adults have already been recovered as a result of feeding experiments involving plerocercoids taken from wall eyes from Lake Winnipeg and Lesser Slave Lake. The other dogs have been infested too recently for the recovery of adults and are being kept in animal quarters. Three new cases of human infestation with the broad tapeworm have come to the author's attention during the last month. In six of the fourteen known native cases, the patients were of Jewish parentage. The ages of thirteen of the patients are known, and none of these are over eleven years old. Wall-eyes from each of the lakes mentioned are being shipped to several of the large cities in the United States, except during the closed seasons, which generally are short but vary in length for different lakes—*J Am M Ass*, 1928, xli, 396.

POSTOPERATIVE PULMONARY COMPLICATIONS*

BY EDGAR RAE, B A , M B ,

Toronto

THE postoperative complications involving the respiratory tract have always caused the surgeon considerable anxiety. In spite of improvements in the methods of administering anæsthetics, careful pre-and post-operative care, the refinement of operative technique, and the rapidity of operative procedure, apparently the number of such cases has not been reduced materially.

The complications consist of lobar and broncho-pneumonia, acute bronchitis, pleurisy, empyæma, embolism and mediastinitis. An analysis of the complications following abdominal operations shows that they most frequently follow septic cases and are rather rare following clean pus-free operations. This would lead one to think that it may be due more to the septic condition than to ether, or any other cause often given as an etiological factor.

Pneumonia is the most frequent and serious complication, especially the cases developing within the first two days. These cases have been often called "ether pneumonias," but improperly so, for we know that, while some of them belong to the irritation class, they are not necessarily the result of anæsthesia. In this group there is usually a sharp rise of temperature (102-104 degrees), usually without chill, associated with frequency of respiration, cough in the majority of cases, with or without muco-purulent and occasionally rusty sputum, and in many cases pain in the chest. The physical signs appear within twenty-four hours, perhaps only localized râles and diminished breath sounds, which clear up in a few days or go on to definite dullness and bronchial breathing. The cases recover in from three to ten days, or end fatally.

The cases developing during the surgical convalescent period, *i e*, the 3rd to the 7th day differ little in clinical course from non-surgical pneumonia, except that a good many of them do not have subjective symptoms. Breathing is quiet, slightly accelerated, the colour good, pyrexia moderate, but the physical signs are

still present. These cases do well and are not apt to be severe in type and outcome, unless associated with some exhausting surgical condition or secondary to a suppurative process in the abdominal cavity.

We have also another group occurring during the convalescent period. They are really the result of embolism with resultant pulmonary infarction. Here, the onset is sudden, with severe and persistent pain, slight cough and slight blood-stained sputum. These cases are fortunately infrequent, because they are nearly always fatal, one of the tragedies of surgical experience. Bronchitis occurs frequently but it is exceptional for it to result fatally. Pleurisy may occur as a primary lesion, or as a sequela of pneumonia, usually in the second week. Pleurisy with effusion and empyæma occurs earlier and usually follows a localized or general upper abdominal peritonitis, affording an immediate source of infection by the lymphatics. Empyæma of itself rarely follows a postoperative pneumonia.

Lung-abscess occurs very seldom in general surgery. In nose and throat surgery pulmonary abscess is a complication by reason of the likelihood of aspiration of foreign material, *e g*, septic plugs from infected tonsils. Mediastinitis is highly fatal. It is always a potential complication in surgical procedures on the lower neck, in the presence of sepsis, or when instrumentation of the œsophagus, trachea and bronchi is carried out.

ETIOLOGICAL FACTORS

Inhalation anæsthesia, especially ether, has been blamed from time immemorial as the cause of postoperative pneumonia and bronchitis. While it is true that a few cases may be justly attributed to the irritation of anæsthetic, the majority cannot be so explained. There is much evidence to bear this out. Complications follow all types of anæsthesia, local and spinal as well as inhalation. Gottstein and Heule, for instance, reported in a series of laparotomies that more pneumonias followed local than general anæsthesia, though with less

*Read before Section of Anæsthesia, Academy of Medicine, Toronto, April 19th, 1928

mortality It must not be forgotten, however, that oftentimes local anæsthesia is chosen because of the grave condition of the patient or because of evidence of recent respiratory tract infection, either one possibly being the factor responsible for the pneumonia Further evidence that ether is not always responsible for respiratory tract complications is found in the circumstance that many cases in which ether is taken badly, where there is much mucus, dyspnœa and cyanosis involving an obstructed airway to the lungs, do not develop any trouble, and, conversely, the complications sometimes follow technically perfect anæsthesia This, however, does not lessen the responsibility of the anæsthetist, or the desirability of a smooth anæsthesia free from cyanosis, vomiting and mucus Aspiration of throat contents, *ie*, mucus and food mixed with pathogenic bacteria such as the pneumococcus and streptococcus, undoubtedly at times is a contributory factor On the other hand, if aspiration alone were of great moment, I am sure that more pneumonia and lung-abscess would follow tonsil operations than are reported, inasmuch as in this type of case there is excellent opportunity for the descent of foreign material into the bronchi

TYPE OF OPERATION

How much responsibility attaches to the type of operation and the location of the operative field is a matter of opinion Statistics show that complications follow abdominal operations more frequently than elsewhere This may reasonably be accounted for by the diminished aeration of the lung and the inability of the patient to cough out mucus freely, following, or owing to, the limitation of diaphragmatic excursion due to the trauma of rough retraction, or the application of tight binders and dressings, or abdominal distension, or the pain which results from incisions close to the ribs

Sepsis is also a very important predisposing factor and acts either by impairing the patient's power of resistance or affording a focus from which infection may travel to the lungs by the blood stream or the lymphatics, presumably as septic emboli This does happen particularly in septic conditions in the upper abdomen, where there is a possibility of direct extension from the subphrenic viscera and peritoneum The anatomical channels of communication by the lymphatics and venous system are well established The lymphatic vessels from the mesentery, liver and

stomach pass directly through the diaphragm to the anterior and posterior mediastinal nodes and thence into the bronchial lymph nodes, or they pass into the thoracic duct and ultimately in this way drain into the lungs Then the mesenteric veins which are tributary to the portal system anastomose freely with the gastric, œsophageal, retroperitoneal, and hæmorrhoidal veins, and in this way afford a certain though indirect portal of entry to the lungs However, bacteriological, pathological, and clinical findings lead us to believe that embolism is an infrequent factor Whipple and Cleveland found that the pneumococcus was responsible for the majority of postoperative pneumonias, and, inasmuch as the respiratory tract is the habitat of the pneumococcus and not the abdominal cavity, the large number of pneumococcus cases occurring in abdominal operations cannot be explained on the basis of septic embolism We could account for streptococcal pneumonia in this way, but why should we not have, as we do not, a large number of colon bacillus infections of the lungs, since this is the predominant organism in abdominal sepsis? Blake and Cecil, in experimental work with monkeys, in which animals pneumonia develops and runs a clinical course comparable in every way to the human type, found that the trachea and bronchi are the portals of entry for the bacterial invasion of the lung, whether by the pneumococcus, streptococcus or influenza bacillus From the trachea the organisms proceed by the lymphatics to the bronchial lymph-nodes at the hilum of the lung, and thence by the lymphatics about the vessels and bronchi to the interstitial tissue, beginning at the hilum and extending to the periphery of the lung The alveoli are involved secondarily

A review of the foregoing statements would lead to the conclusion that there is essentially no predisposing cause for the postoperative pulmonary complications It is felt that we have to do with that indefinable, intangible thing which we term "the patient's vitality or power of resistance," and it is our duty as surgeons and anæsthetists to be more on the alert, especially with precautionary measures

BEFORE OPERATION

A careful examination with special reference to the respiratory tract should be made An infection recently subsiding or subacute, such as a coryza or laryngitis, can and does cause further complications after operation. Certainly no

person thus affected should be operated upon unless in extreme emergency. Patients should be kept in bed the day before operation, if possible with sufficient blankets on the bed, and suitable warm clothing, avoiding draughts at all times and subjected to careful oral hygiene.

CHOICE OF ANÆSTHETIC

Meet the choice of surgeon and patient in so far as it will not interfere with your own judgment. But do not attempt to adjust a patient to a given anæsthetic. The anæsthetic must be adjusted to the patient.

DURING OPERATION

Further precautions against draughts and chilling of the patient by the use of cold solutions should be taken. The operating room should be warm, avoiding all unnecessary delays during operation. The patient should not leave the operating room without a dry warm nightgown and properly warmed blankets.

The surgical technique includes the assurance of careful asepsis, perfect hæmostasis, avoidance of undue traumatism of tissue. The dressings, especially those over the upper abdomen should be applied snugly, but not so firmly as to restrict the respiratory movements.

AFTER OPERATION

Further protection against exposure should be made. Free movement in bed is to be encouraged, with elevation of the head and thorax from the flat position, especially where there is a tendency to hypostasis of the lungs.

If pneumonia or other pulmonary complications develop, the principles of the treatment of non-surgical pneumonia and lesions should hold sway. Those essentials are good nursing, plenty of fresh air, forcing of the fluid intake, especially water, enough digitals or caffeine to support the heart, and enough sedative to relieve anxiety and pain.

Reviewing the histories of some sixteen hundred cases operated on at Grace Hospital in 1927,

postoperative pulmonary complications were found in eleven cases. Briefly these cases were —

SUMMARY OF CASES

1 A man aged 59 years herniotomy, congestion of the base of the lungs after seven days, normal three days later.

2 A man, aged 40 years hæmorrhoidectomy, dry pleurisy ten days after operation, recovery.

3 A girl aged 14 years appendicectomy, congestion of the base of both lungs after three days, normal two days later.

4 A man aged 22 years submucous resection, some congestion of lungs next day, normal in three days.

5 A woman aged 25 years appendicectomy, dry pleurisy eleven days later, normal in five days.

6 A man aged 65 years herniotomy, strangulated hernia, death from pneumonia and myocarditis four days later.

7 A woman aged 38 years curettage, incomplete abortion, a septic case with phlebitis of both legs, two blood transfusions ninth day, pleural effusion, culture, negative, died from septicæmia five weeks after admission to hospital.

8 A man aged 20 years mastoiditis sinus thrombosis and peri-sinus abscess, death from influenzal pneumonia in three weeks.

9 A woman, aged 30 years appendicectomy, right lobar pneumonia two days after operation, death two days later.

10 A woman, aged 65 years plaster spica for fracture of femur, death from pleuro-pneumonia eleven days later.

11 A woman, aged 80 years plaster spica for fracture of the neck of the femur, broncho-pneumonia, cured.

The last three cases were anesthetized with nitrous oxide and oxygen. The other eight received nitrous oxide, ethylchloride and chloroform with ether sequence.

"We have a great responsibility in functional nerve diseases, and in functional conditions which complicate convalescence from an accident, and this is a great deal more than we, as a rule, realize. We can, by supineness, make chronic invalids, or we may, by throwing the weight of our personality into these cases, restore them to work, and teach the working classes that there is much more happiness in work

than in idleness. Many working men have not yet learned that the only true happiness lies in work. It is wellnigh impossible in accident cases to instil a healthy mental attitude into a man after his case has been set down for arbitration at a county court. In deed, as a rule, nothing can be done in this direction for a man who has consulted a solicitor."—*The Practitioner*, May, 1928.

ELECTRO-THERAPY IN GENERAL PRACTICE

By A. CALDER, M.D.,

Sydney, N.S.

THIS paper is a short report on clinical observations and results in a series of 115 cases of various diseases met in the ordinary run of general practice, in which it was thought that physical therapy, with or without other agents, would produce better, quicker and more lasting results. Where other measures besides physical therapy were used they are mentioned.

In the application and evaluation of any new form of therapy one is apt to be influenced by two general and fundamental sentiments, one or other of which is to be found in every individual, *viz.*, over-enthusiasm or the reverse, and usually results, as published, depend on which one of these sentiments holds sway in the individual making the observations and correlating the results. To obviate this probable source of error, these cases have been submitted to an independent colleague for confirmatory diagnosis, and for observation of the progress and results. So as not to take up too much space, details of general technique have not been gone into. In cases where a brief mention of some points in technique would clarify matters this has been made.

As a sufficient number of cases of the various diseases mentioned below have not been treated to warrant a definite opinion on the value of this form of therapy, the idea prompting this paper is merely to stimulate interest in this addition to the physician's armamentarium, so that its true value may eventually be measured, not from the mouths of high-pressure salesmen, but in terms of clinical experience.

The equipment used consisted of a medical and surgical diathermy apparatus and a quartz mercury-vapour (air-cooled) lamp. Briefly, the general technique, as regards ultra-violet rays, was as follows—

All patients were divided into two classes for the purposes of dosage: (1) blondes all with blue eyes, irrespective of the colour of the skin; (2) brunettes all others. All patients were weighed and a general examination given before beginning the treatments. The distance of the

patient from the lamp (burner) was kept constant (thirty inches), except in rare circumstances, but the time was varied.

In all dermatological cases, excepting those in which external causes could be definitely established, it was assumed that the skin condition was but the local manifestation of a generalized disease, affecting the organism as a whole. For that reason, attention was given, not only to the local lesion, but to the whole organism, in regard to foci of infection, diet, elimination, etc. For example, in acne vulgaris the comedones were expressed, and, after the removal of all grease and dirt, the sites were irradiated and then the body was irradiated as a whole. Advice was given as to diet and elimination, as well as treatment for any attendant anæmia.

During the period under review (three months), the following were treated, taking the diseases in alphabetical order—

ACNE VULGARIS

Four cases. The disease in all cases was confined to the usual location—face, front and back of the chest. These received a total of twenty-six treatments, an average of six and one-half per case. No drug was used locally, and in only one case was it thought necessary to give iron for the accompanying anæmia, in the form of Bland's pills. All the cases cleared up thoroughly to our own satisfaction and to that of the patients.

ALOPECIA AREATA

There was one case of this condition, in a young man of nineteen years of age, who had about twelve patches varying in size from a ten cent piece to a silver dollar on various parts of the head. The head was shaved as closely as possible, and the ultra-violet ray was applied by means of the air-cooled lamp, at twelve to fifteen inches from the scalp, so as to produce a first degree plus erythema. After five treatments new hair could be detected growing in these bald spots.

ARTHRITIS

The cases were divided into two general classes, *viz*, traumatic and non-traumatic. Eight traumatic and nine non-traumatic cases were treated, the non-traumatic being considered rheumatic, gonorrhœal, or otherwise. Of the traumatic cases an average of five treatments (diathermy) were sufficient to give freedom from pain, and to restore the joint to normal. Most of the traumatic cases were sprained ankles. Besides receiving diathermy, all cases were strapped with adhesive plaster. There was no loss of time from their occupations, even in the very severe cases. Of the nine non-traumatic cases four were distinctly gonorrhœal, and yielded to an average of ten treatments by diathermy to the joint and to the urethra, and in the female to the cervix and urethra. The rheumatic cases, as a rule, required a greater number of treatments, averaging about fifteen per case.

ASTHMA

One case. This received twelve treatments with ultra-violet rays, together with calcium by the mouth, resulting in a complete cessation of spasm, disappearance of the cough, and a gain in weight and appetite. Incidentally, this case had general psoriasis as well, and, to our surprise, on completion of the treatment for asthma, his psoriasis had cleared up completely.

BRONCHIECTASIS

One case was treated during the afebrile periods with ultra-violet rays (general body raying), for its general effects. After seventeen treatments there was noted a feeling of well-being, an increase in appetite, increase in weight of two pounds, but as other measures, *e.g.*, postural drainage and tonics, were used simultaneously, it is difficult to say what proportion of good, if any, was due to the ultra-violet ray.

CANCER

One case of carcinoma of the lip was treated, in a man of eighty-two years, which had recurred after removal by a so-called "cancer doctor" some years before. The growth was coagulated *in situ* and allowed to slough, which event occurred in ten days, in three weeks from the date of treatment the area was completely healed, leaving a soft pliable scar. By this

bloodless method, it was felt that any chance of metastasis was lessened or prevented altogether. Besides, the operation was an office procedure. A local anæsthetic was used.

ECZEMA

Eight cases of eczema of various parts of the body were treated. They ranged, in regard to the clinical picture, from the weeping to the dry scaly form. The severe cases (5) received a total of one hundred and ten treatments in the form of local ultra-violet ray treatments and general body raying. In dealing with this series the lesson was impressed that the ultra-violet ray is capable of doing harm, and should only be administered by or under the supervision of a physician experienced in the use of such agents. This was a case of eczema of the chin of the sub-acute form. The patient, in question, was getting along nicely on regular distance application, but it was thought that the lesion was not disappearing fast enough, so when the patch was reduced to the size of a five-cent piece we doubled the time and shortened the distance by one-quarter, protecting, of course, the adjacent normal tissue. To our surprise, the day after, his eczema was worse than it ever was and was itching and weeping. The treatments were stopped, and, after about a week, the superimposed acute condition disappeared, and slow and minimum raying brought the case to a successful conclusion. In one very bad example of eczema of the hand the lesion cleared up nicely, but recurred two weeks after cessation of the treatments. All eczema cases received calcium in some form, on the strength of the repeatedly demonstrated fact that there is often a lowered blood calcium content in these cases.

The lesson learned in these cases was that the acute and sub-acute forms were more amenable to treatment (at least by the air-cooled lamp), and that the dry scaly forms had to be rayed very heavily to produce a third degree erythema and that all scales had to be removed before success could be achieved. All the cases cleared up completely, excepting one.

EPIDIDYMITIS

One case was treated by diathermy and, was completely relieved after six treatments. The patient was not confined to bed and wore a suspensory bandage. The treatments were

given daily, and after six the swelling subsided, and patient was able to work.

FURUNCULOSIS

Four cases of this condition were treated by local and general body raying. One case, after twelve treatments, showed some improvement, but it was not a complete success. This was a case referred to us in which everything else had been tried for repeated boils in the nose. A thorough examination failed to reveal any underlying condition. Complete success was probably due to lack of the proper apparatus. A water-cooled lamp, with quartz applicator, would have produced more gratifying results.

One patient who had been afflicted with boils continuously for the past three years, has not had any for the past three months, after five treatments, the longest period of relief in three years.

GENERAL RUN-DOWN CONDITION

Six such cases were dealt with, in women of the large-family and hard household-workers type, who presented no special lesions, but complained of lassitude, headache, and a feeling of being "all in." These cases were given ultra-violet ray, (general body raying). They all showed, after an average of ten treatments, increase in weight and appetite, and a feeling of well-being. The feeling of well-being may, of course, be psychological, but the increase in weight and appetite must be credited to the ultra-violet ray.

CHRONIC GONORRHOEA

During the period twelve cases of chronic gonorrhœa in male and female, of six months to three years standing, were treated. They all had diathermy to the urethra, prostate, vagina and cervix, as the case might be. All showed, after the first two or three treatments, increase of discharge which then became gradually less, until there was complete cessation, the male missing even his "morning drop." It was found also that the urethra or cervix could be treated up to 108° F. in most patients without discomfort. All were discharged cured, after showing three negative smears from the urethra or cervix.

HÆMORRHOIDS

Two cases of external, and one of internal, hæmorrhoids were treated by electro-coagulation with the Bierman clamp. The technique followed was that of Dr. Wyeth, of New York. The first case had no occasion to lie up. The second, owing to an associated prolapse of the rectum, had to lie up for one week. The third, of internal associated with external hæmorrhoids, had no discomfort, and was able to work next day. We are convinced that this will be the standard method for the removal of hæmorrhoids in time, as it entails simplicity, no loss of time, no pain, very little if any reaction, and less expense. Two per cent novocain was the anæsthetic used in these cases.

HIGH BLOOD PRESSURE

One case of essential hypertension was treated, in a man of forty-six years of age, in whom the systolic blood pressure was 220, and diastolic 120. The systolic was reduced to 180 and the diastolic to 110, after treatments by auto-condensation. There was however a gradual return to 220/120 six weeks after the treatment had been stopped. The mode of living, diet, and elimination played no part in the case, during or after treatment, as the same regimen was followed as closely as possible during and after treatment as before it was started. The effect on blood pressure was transitory so far as can be judged from this one case.

IMPOTENCE

Three cases of impotence in young men twenty-six to forty-five years of age, were given ultra-violet ray and diathermy, in the form of sharp sparks over the lumbar vertebræ, with the Oudin current, after drugs had been given a fair trial. They had an average of ten treatments each with the result that all three cases showed marked improvement after six treatments.

LUMBAGO

Two cases of this condition were treated by diathermy. In both cases improvement was noticed immediately after the first treatment, and this improvement continued until the pain completely cleared up. The two cases had twenty-two treatments, an average of eleven per case.

MOLES

Two cases of moles of the back of the neck were treated by desiccation with the Oudin (monopolar) current. No anæsthetic was used and one application was sufficient.

MUCOUS COLITIS

(Associated with *Neurasthenia*)

This was a case that had been the rounds of various doctors. He had had his appendix removed for some vague pain in the abdomen. His case was diagnosed as neurasthenia associated with mucous colitis. He was given colonic lavage (Battle Creek method), and ultra-violet ray and diathermy to the colon by means of electrodes to back and abdomen. After eighteen treatments he was restored to health, gained in weight and appetite, and went back to work.

NEURALGIA

Three cases of neuralgia of the ophthalmic division of the fifth nerve were treated. In one the worst, both ultra-violet ray and diathermy were applied and marked improvement was obtained after twelve treatments. Previously this patient had been taking about sixty grams of aspirin every twenty-four hours for about two months to obtain relief. No drugs were given with treatment. The other two cases had diathermy only with complete relief.

NEUROSIS (*Climacteric*)

The three cases treated had the usual nervous symptoms associated with the menopause. General body baths, with ultra-violet ray were given in all cases and also calcium. The three cases had a total of forty-five ultra-violet ray treatments, and showed improvement in their mental state, gained in weight and had a brightened outlook on life.

NEURASTHENIA

Under this head were placed all cases in which there was a multiplicity of symptoms, but no lesion to be found. Six such cases had a total of eighty treatments with ultra-violet ray, with the addition of diathermy when necessary for pain. All the cases, except one, were restored to normal health, with a feeling of well-being, gain in weight and appetite, and cure of insomnia. All the cases received phosphorus and calcium in some form, in addition to the

treatments. One case, with an associated cryptic tonsil, improved at first, but later relapsed. Subsequent removal of the tonsil and further treatment did not seem to help matters. This case had more than thirty treatments.

NEURITIS

This was a case of neuritis of the right arm in a woman about fifty, who had suffered from this condition for about one year, causing a great deal of insomnia so that she had to be given narcotics. After fifteen treatments with mild diathermy and auto-condensation her neuritis disappeared, and she is now free from all symptoms and sleeps well.

NEVUS

There was one case in a child of three years, with the usual port-wine colour extending over the forehead to the eyebrow and down to the cheek bones on the right side, with hair covering the area. This area was desiccated with the monopolar current, and the area destroyed, leaving a scar which in time we hope will scarcely be noticeable. The result here was very satisfactory indeed.

PARONYCHIA

One case was treated by means of the ultra violet ray with complete success.

PLEURISY

During this period three cases of pleuritis sicca, which had a total of twenty-two treatments by diathermy to the affected part were completely relieved.

POST-FRACTURE CONDITIONS

Two cases of post-fracture conditions, *e.g.*, stasis around the joint, restricted movements, swelling and pain, were treated by diathermy and massage. Both cases showed rapid diminution of these signs after an average of five treatments.

POST-OPERATIVE PELVIC ADHESIONS

One case, which had been operated on for "appendicitis" and "ovarian trouble" some years before. She still complained of pelvic pain, and was subsequently operated on twice for pelvic adhesions with no relief. On examination, no pathological condition could be found, and the patient was against further

exploration Diathermy was advised, in the hope that relief might be obtained After ten treatments, by means of diathermy through the vagina and lower abdomen, the patient was completely relieved

PNEUMONIA (*Lobar*)

One case This was a case of very virulent pneumonia, infection involving both lungs, with greenish red expectoration, etc After the usual treatment by means of topical applications and medicines, the patient continued to go down hill, Cheyne-Stokes respiration being present, the pulse becoming weaker and intermittent, and the patient becoming very cyanotic and delirious Diathermy was tried as a last resort, one thousand milliampères were given for forty-five minutes to the chest anteriorly and posteriorly by means of two electrodes Fifteen minutes after the application the patient complained of being very warm, perspired freely, and the cyanosis disappeared, the cheeks becoming quite red At first there was a slight increase in the pulse rate, from 140 to 150 per minute, but it became more regular and the quality was better The Cheyne-Stokes feature of the respiration disappeared also Treatment was then discontinued, but in one hour the danger signals of Cheyne-Stokes respiration, etc, returned The patient was then given another forty-five minutes treatment, but the response was not so good as at the first application Patient eventually died five hours after the last treatment

PSORIASIS

Of two cases of this disease, one was spontaneously cured during treatment for asthma, as mentioned before, after twelve treatments by ultra-violet ray The other, a case of general psoriasis in a young man of eighteen years of age, completely cleared up after eight treatments by the ultra-violet ray Both had calcium in some form.

PRURITUS VULVÆ

One case of this distressing condition in a married woman was treated by means of the ultra-violet ray The first few treatments were sufficient to allay the itching, and after eleven more the condition was completely relieved

RICKETS

There were two cases of rickets in children, eighteen months and two years old, respectively

One, a coloured child, could not sit straight and had no desire to get up or play Soon after the third treatment with the ultra-violet ray the child became brighter and made attempts to stand up He was generally keener, enjoyed his meals better, and gained in weight An associated bronchitis also improved with no other treatment This child had five treatments but was forced to discontinue owing to the illness of his mother, but the improvement was most marked

The other, a girl (white), had only one treatment, so that the effect cannot be appreciated.

SARCOMA

One case of sarcoma of the middle turbinate, in a woman fifty years of age, was treated by electro coagulation In this case, which had been going on for six months, the growth had completely blocked the right nares The portion blocking the nares was destroyed, so as to permit investigation of the posterior nares The operation was bloodless, and after about two weeks it was found that the antrum and hard palate were involved Under a general anæsthetic as much of this as possible was destroyed, and though a cure is not possible the growth has certainly been retarded and the patient saved from being exsanguinated from the many and frequent hæmorrhages she had been having

This was a growth that no surgeon, however expert, would have attempted to remove, as the operation would have been mutilating at best and metastases would most likely be formed from the carrying of malignant cells by the blood The procedure was bloodless, and accordingly, there was no danger of metastasis resulting from the operation

SCIATICA

Of four cases of this condition treated, two were completely relieved after a total of twenty treatments by diathermy, one was partly relieved, and one obtained no relief It is only fair to mention that the case that was not relieved had a mild pyorrhœa, for which removal of the teeth was advised, but the advice was not acted upon

SPERMATORRHOEA

One case of this condition was treated by diathermy to the prostate and testicle. After ten treatments there was a much diminished "loss," but the condition was not completely cured. This patient also had calcium and phosphorus.

VARICOSE ULCER

Four cases of this condition, varying from single small superficial ulcers to many deep craters in each case, were treated. The four cases received an average of ten treatments each with the ultra-violet ray. No case was confined to bed with elevation of the limb. A supporting crepe bandage was however used in all cases, and all had calcium in some form. No topical application was used, excepting the painting with 2 per cent mercurochrome before each exposure. In all cases it was noticed that the terrible itching ceased after the first treatment, and the pain was relieved, or disappeared completely, after the second or third treatment. Any associated eczema in the region of the ulcers cleared up completely. An elastic stocking, following the healing of the ulcers was advised in all cases.

WARTS (*Common and Venereal*)

Eight cases of warts of various parts of the body were treated by desiccation with the Oudin current. One application was sufficient in all, and in only one case, of the venereal type, involving the entire corona, was it necessary to use a local anæsthetic. In our opinion it offers an easy and quick method of removing these annoying things, far superior and safer than the old way, with applications of caustics such as nitric acid.

CONCLUSION

Following our limited experience with this form of therapy we are of the opinion that it offers many advantages over other forms of therapy in the treatment of many conditions that come within the purview of the general practitioner, but there are two essentials, apart from good equipment and technique, namely, perseverance on the part of the patient and stick-to-it-iveness on the part of the doctor.

I take this opportunity of expressing my grateful thanks to Dr W. J. Egan for valuable and helpful advice during the period under review, and to Miss Bessie McNeil, R.N., who assisted in carrying out the treatments.

PNEUMOCOCCIC MENINGITIS*

By W. R. KENNEDY, B.Sc., M.D., C.M.,

Montreal

A RECENT series of cases of pneumococcic meningitis admitted to the medical service of Dr. A. H. Gordon and Dr. C. A. Peters in the Montreal General Hospital forms the basis of this paper.

Whether one can classify such cases into primary and secondary groups is debatable. Just as one speaks of primary pneumococcic peritonitis, so there are cases which must be called primary meningitis of pneumococcal origin. The larger group, however, is made up of cases that are secondary to pneumococcal infection elsewhere. They can be arranged as follows: (a) Cases with original foci of infection, acute or chronic, in paranasal sinuses, middle ear, and

mastoid areas, (b) Cases following fracture of the base of the skull, especially those that open a path of infection through the sinuses, middle ear, or pharynx, (c) Cases in which there is a preceding blood-stream infection. This last group is again subdivided into primary and secondary septicæmias, the latter being best exemplified by the septicæmia that complicates a lobar pneumonia. This is in accord with Baldwin and Cecil's conclusion that, just as the commoner pyogenic infections are usually localized but at any time may progress to the septicæmic stage, so may pneumonia lead to pneumococcic septicæmia.

The prognosis of pneumococcic meningitis is exceptionally grave. Kolmer reports a mortality of 100 per cent in 14 cases of various types.

*Read at a meeting of the Montreal Medico-Chirurgical Society, March 30, 1928.

Schottmüller records a similar issue in 100 cases. Cole has observed 8 cases of meningitis secondary to pneumonia out of a total number of 770 cases, and all were fatal. It is not, however, uniformly fatal, for authentic instances of recovery are found scattered throughout the literature. Jemma in 1896 reported the first such case, and more recent recoveries are quoted by Cumming, Campbell, Ratnoff and Litvik, Simpson, Syngé, Douthwaite, Harkavy, Globus and Kasanin. Cecil and Baldwin point out that the presence of infection in the blood is an important determining influence on prognosis in a pneumonic infection. They found that the total mortality rate for thirty-seven patients with pneumococcus pneumonia with positive blood cultures was 78.3 per cent, in contrast with a death rate of 10 per cent in seventy cases with sterile blood cultures.

The therapeutic procedures followed in cases of pneumococcic meningitis with recovery have been (1) Intrathecal serum therapy, as in the case reported by Simpson. (2) Repeated lumbar and cisterna magna punctures, alone or combined, as recorded by Globus and Kasanin, and Syngé. Rolly also reports a case of pneumococcic meningitis coexistent with pneumonia in a child in whom sixteen lumbar punctures were performed and 600 c.c. of spinal fluid withdrawn, with a favourable outcome. (3) Laminectomy for continuous drainage, as suggested by Hill and Rainey and Alford. (4) The injection of Morgenroth's optochin hydrochloride by the method of Ratnoff and Litvak, spontaneous recovery has been recorded by Parkinson.

The following case reports represent various types of pneumococcic meningitis.

CASE 1

Male, aged 15 years, admitted January 13, 1928.

Complaints—Vomiting, convulsions, unconsciousness.
Family history—Irrelevant.

Personal history—The patient had been admitted to the Montreal General Hospital on December 20th, subsequent to a head injury, and was discharged on January 3rd, in good health, with a diagnosis of contusion and concussion, and an x-ray finding of fracture of the base of the skull in the right frontal and ethmoidal regions.

Present illness—He was apparently well until the night of January 12th. That night and the following day he vomited on several occasions, and also complained of right-sided earache. On the next afternoon he had a convulsion and until admission that night had been very restless and semicomatose.

On admission his temperature was 104°, pulse, 116, respirations, 32. He was semi-comatose and was tossing restlessly in bed. The pupils were dilated but active. Neither herpes nor nasal discharge was noted. The right ear drum was reddened and bulged somewhat. The glands, throat, lungs, heart and abdomen were negative. The blood pressure was 132/78. No cranial nerve lesion

was made out. The extremities showed free movements, abdominal reflexes and knee jerks were absent. Bilateral Kernig sign and rigidity of the neck were present. The urine was negative. The white blood cells numbered 24,000 per c.mm. Lumbar puncture, under anaesthesia, revealed a turbid fluid, the cell count of which was 19,000 polymorphonuclear cells predominating. Scattered Gram-positive, lancet-shaped diplococci were found in the direct smear. Paracentesis of the right ear was done and only a serous exudate escaped, culture of which yielded *S. aureus*. On culture of the spinal fluid pneumococci were isolated. Mastoid drainage on the right side was performed but only an acute hemorrhagic condition without pus was found. Death occurred on January 15th after a four days' illness.

The *clinical diagnosis* was pneumococcic meningitis (type IV), fracture of the base of the skull, right acute otitis media.

Autopsy findings—Meningitis with purulent exudate at the base and spreading to the cortex, linear fracture of the base of the skull, involving the right frontal sinus and extending along the floor of the anterior fossae (this was probably the path of infection). The right frontal, ethmoidal and sphenoidal sinuses contained pus and pneumococci were cultured from it, the right mastoid area presented granulation tissue and some pus, but this was sterile on culture. Pneumococci were isolated from the meningeal exudate.

CASE 2

Female, aged 66 years, admitted January 6, 1928.

Complaints—Unconsciousness.

Personal history—The daughter stated that her mother had had good health, except for neuralgic pains about the face for the past year. About December 26th, 1927, the patient developed a slight chest cold, and also complained of backache and of sore eyes. She remained in bed from the onset of the illness. For a few days she had a right-sided earache, but this disappeared on January 3rd without discharge of pus. For ten days periods of perspiration had alternated with those of chilly sensations. Nausea appeared on January 5th, with vomiting the following day, and shortly afterwards unconsciousness which persisted till admission.

On admission, the patient was comatose but resisted movements. The pupils were small, inactive and equal. The throat, lungs, heart and abdomen were negative. The blood pressure was 150/80. No cranial nerve lesion was made out. There was movement in all limbs, but she did not respond to questions. The knee-jerks were feeble. There was plantar flexion, also a bilateral Kernig sign and rigidity of the neck. The right ear drum showed some redness, but there was no tenderness over the sinus. The urine was negative. The white blood cell count was 12,800 per c.mm. On lumbar puncture, spinal fluid escaped, in which Gram-positive diplococci were found in direct smear and later were isolated in culture as type IV pneumococcus. The otolaryngologist confirmed the redness of the right ear-drum, with loss of lustre and light-reflex, but, as there was no sagging of the posterior wall, he did not consider the mastoid to be a focus of infection. On January 8th the patient developed some feeble clonic spasms in right arm, and also a sanguino-purulent discharge from the right nostril. In view of the history of neuralgic pains in the face, the presumption was that the meningeal infection arose from a paranasal sinusitis. Death occurred on the third day of meningitis.

The *clinical diagnosis* was pneumococcic meningitis, and paranasal sinusitis.

Autopsy showed purulent meningitis, sphenoid sinusitis, and right mastoiditis. The mastoid area was less involved than the sphenoid sinus. Pneumococci were recovered from each of the above lesions.

CASE 3

Male, aged 10 years, admitted March 17, 1928.

Complaints—Headache, vomiting, restlessness, delirium.

Family and personal histories were irrelevant.

Present illness—On March 16th the patient com-

plained of headache about noontime, and vomited on returning from school in the afternoon. He was put to bed and fever was noted. Vomiting occurred several times that evening and he soon became restless and delirious. These symptoms gradually progressed till he was admitted to hospital on the night of March 17th. No history of accident or earache.

On admission, his temperature was 103°, pulse, 108, respirations, 40. He was delirious and was tossing about in bed, resisting all movements. Photophobia was present, the pupils were equal and active. No herpes. The ears, throat, heart, lungs and abdomen were negative. No cranial nerve involvement or motor paralysis was found. The knee-jerks were absent, plantar reflexes showed no reaction. No clonus. Bilateral Kernig sign and rigidity of the neck were present. Lumbar puncture showed a pressure of 30 mm of mercury, and 12 c.c. of turbid spinal fluid were removed slowly. The cell count was 500 c.mm., 75 per cent of which were polymorphonuclear cells. Gram positive lancet-shaped diplococci were found in direct smear, and type IV pneumococcus was reported on culture. One hour after lumbar puncture the patient became suddenly cyanosed and died, after an illness of thirty-eight hours.

Clinical diagnosis—Fulminating pneumococcal meningitis, so called "idiopathic." No autopsy was allowed.

CASE 4

Male, aged 50, admitted February 9, 1928

Family and personal histories—Irrelevant

Present illness—This patient was admitted on the tenth day of illness, with a frank lobar pneumonia. The rest of the physical examination, including the urine, was negative. The white blood cell count was 17,000 per c.mm. Sputum typing showed type IV pneumococcus. The temperature on admission was 101°, pulse, 100, and respirations, 40. The following day the temperature and respirations had fallen to normal. On this day a routine blood culture was taken, and four days later was reported as positive for pneumococcus, but owing to an accident, typing was not done. From the fifteenth to the eighteenth day of illness there was a remittent fever, associated with chills and profuse perspirations. There were no pulmonary signs that could account for this course. On the nineteenth day the patient was somewhat drowsy and listless. An apical systolic murmur was then noted for the first time. The pupils were small and sluggish. Slight left facial weakness and some stiffness of left arm and leg were noted. A left-sided Babinski sign was elicited, as well as a bilateral Kernig sign and rigidity of neck. A blood culture was again made and was reported the following morning as positive for pneumococci. A lumbar puncture was then done and clear fluid escaped, the cell count of which was twenty, and globulin was absent. On culture, no growth was obtained. The next day a complete left-sided hemiplegia was found, with weakness of the right upper extremity. The clinical interpretation of this case was then considered to be a spreading cortical meningitis, as a part of a pneumococcal septicæmia, with an acute mitral endocarditis of the same origin. The possibility of the cerebral features being due to an infected embolus was thought unlikely, on account of the slowness of the onset of symptoms. On February 20th the pneumococcus from the bloodstream was reported as the type I strain. There was gradual extension of the cerebral symptoms, and, with little hope of obtaining any benefit, the patient was given 75 c.c. of type I antipneumococcal serum intravenously. Death occurred on the 21st day of illness.

Clinical diagnosis—Lobar pneumonia, pneumococcal septicæmia (type I), pneumococcal meningitis, acute mitral endocarditis of pneumococcal origin.

Autopsy findings—Lobar pneumonia, affecting the right upper and middle lobes in resolving stages, endocarditis with recent vegetations on the mitral valve, multiple infarcts in the spleen, purulent meningitis, the exudate covering the right cerebral hemispheres much more extensively than on the left side, from this exudate pneumococci were isolated.

CASE 5

Male, aged 29 years, admitted on March 3, 1928

Complaints—Weakness, general malaise, fever, painful left eye.

Family and personal histories—Irrelevant

Present illness—The onset of the present illness dated from February 24th. According to his physician, the course had simulated in many respects that of typhoid fever, as evidenced by his general appearance and the development of a palpable spleen, but the temperature had been intermittent with ranges from normal to 104° daily, and was accompanied by chills and profuse sweats. On March 1st an acute pain developed in the right eye, and since then that eye had become extremely reddened. The patient also complained of severe frontal headache on admission.

On admission, his temperature was 103°, pulse, 118, respirations, 32. He was semi-stuporous and typhoidal in appearance, was able to give part of his history, but had to be continually aroused during the history taking. The left eye presented an intense degree of panophthalmitis. There was no tenderness over the sinuses, and the ear-drums were intact. X-ray examination of the sinuses was negative. Herpes was not present. The tongue was dry and coated with sordes. The lungs and abdomen were negative, except for a easily palpable spleen. There was a loud apical systolic murmur, which was present when first seen by his physician, but was observed to have increased in intensity during the progress of his illness. Roseola, petechiae and tender points on finger-tips were absent. Superficial twitchings were noted in the right arm. The cranial nerves were intact. No loss of motor power and no pathological reflexes were found, except for a bilateral Kernig sign and rigidity of the neck. The urine was negative. The white cell count was 19,000 per c.mm. The spinal fluid was turbid, the cells numbering 1,000 per c.c., 80 per cent of which were polymorphonuclear in type. The Pandy and Ross-Jones tests were three plus. Gram positive diplococci were demonstrated in the direct smear, and type IV pneumococci were cultured. Blood culture was reported as positive for the same organism. Both results were confirmed on subsequent cultures. Towards the end of the course numerous petechiae appeared on the abdomen and increasing coma developed. The patient was given one blood transfusion and many glucose-saline intravenous injections, and there were repeated lumbar punctures. A total of 400 c.c. of spinal fluid were removed, and as much as 80 c.c. were taken off at one time. Death occurred on the twenty-sixth day of illness and on the tenth day of the meningitis.

Clinical diagnosis—Pneumococcal septicæmia with complicating meningitis, endocarditis, and left panophthalmitis.

Autopsy findings—Basilar meningitis, acute mitral endocarditis, left panophthalmitis, infarction of spleen and kidneys, pneumococci were isolated from the meninges and mitral valve.

SUMMARY

- 1 Five cases of pneumococcal meningitis are reported, all of which were fatal.
- 2 The age incidence varied from ten years to sixty-six.
- 3 The etiological factors in this series are—
 - (a) Fracture of the base of the skull
 - (b) Paranasal sinusitis and mastoiditis
 - (c) So-called primary cryptogenic meningitis
 - (d) A septicæmia following a frank lobar pneumonia
 - (e) A primary septicæmia
- 4 Duration of meningitis in these cases, minimum, 38 hours, maximum, 10 days.

5 In two cases there was acute endocarditis of pneumococcal origin

6 One case showed general pneumococcus infection without localization in the lungs

7 One case of fatal general pneumococcus infection occurred even after almost complete resolution of the primary pneumonic lung

8 A rare complication of metastatic panophthalmitis

In conclusion, I wish to thank Dr A H Gordon and Dr C A Peters for their kind permission to report these cases, and also to express my appreciation to Dr Gordon for his valuable assistance in the preparation of this paper

ECZEMA*

By HAROLD ORR, OBE, MB, DPH,

Edmonton

IN any discussion on eczema it is first of all necessary to define exactly what type of superficial catarrh of the skin one has in mind. Defined by Willan (quoted by his pupil, Bateman) eczema consists of a circumscribed patch of closely set, pin-head sized, deeply formed vesicles, accompanied by itching and burning. At first there is very little inflammation at the bases of the vesicles, but this phase is of short duration, and in the fully developed patch there is redness and swelling.

A study of sections cut from such a patch at various stages of its evolution shows that the earliest change is a dilatation of the superficial capillaries, with a pouring out of lymph from these vessels into the intercellular spaces of the epidermis. This causes spongiosis or œdema, and as the pressure increases the intercellular fibrils break, the cells are pushed aside, and a sterile vesicle is formed in the middle of the prickle cell layer. This enlarges to the size of a pin-head and may rupture on to the surface (weeping eczema). The process may at any time be checked, lymph being poured out of the capillaries in amounts insufficient to cause weeping on the surface and giving rise merely to

œdema. This causes an increase in the rate of multiplication of the cells of the stratum germinativum, and may even cause mitosis in the prickle-cell layer, leading to thickening (acanthosis) and to a derangement of the process of keratinization (parakeratosis) which results in the formation of scales.

There is another type of inflammation of the skin resulting from a specific irritant, such as hair-dye or a plant. In this the inflammation is more diffuse and the vesicles more superficial, not all of one size, and frequently coalescing to form bullæ. The trouble subsides so soon as the irritant is removed and only recurs on the exhibition of the specific irritant. This condition is labelled dermatitis. Etiologically, it differs from eczema in its specificity. There is an idiosyncrasy on the part of the individual. I have two patients dentists, with an idiosyncrasy for novocain, in whom this drug always produces a dermatitis when it comes in contact with the skin, yet neither has ever had an inflammation of the skin from any other cause. This idiosyncrasy may be acquired or inborn. As an example of the acquired type, there is the photographer, who after many years in his profession may suddenly develop an idiosyncrasy for metol or hydroquinon and thereafter a dermatitis de

AN UNUSUAL TYPE OF SUPER-NUMERARY DIGIT

By S H CORRIGAN, M D, C M,

Lampman, Sask

Cases of supernumerary digits of ordinary types are frequently observed. Of the type I present I can find no record. A well known teacher of anatomy in London, after examining the photograph, stated that he had not seen nor heard of such a case as this.

The child (No 179, Lampman Union Hospital, 1926), in all other respects normal, was born of Canadian parents. Both families disclaimed a history of abnormal structures, but I have learned that a child of the father's brother has a supernumerary digit.

The illustration, from a photograph when the child was three months old, shows the pedicle growing from the external lateral aspect of the proximal phalanx of the little finger.

Good tactile sensation was demonstrated over all parts of the structure. The pedicle was entirely flaccid, and could be considerably rotated or elongated by traction, without disturbing the circulation. Amputation was performed when the child, four months old, was

brought to the hospital with the entire structure deeply evanosed.

The terminal portion contained a well developed cartilaginous phalanx. A section of the pedicle showed one main artery and vein.

GIANT-CELLED TUMOUR OF THE NECK OF THE FEMUR OPERATION WITH PROBABLE CURE*

By W G TURNER, M D,

*Royal Victoria Hospital,
Montreal*

A decided advance in classification was made when the word "sarcoma" was dropped from the nomenclature of this class of tumour. Still, it must be seriously recognized that there is progressive local destruction of bone as the growth advances. It is necessary to keep this in mind if we are to improve and gradually perfect a technique which will save the limb and also prevent grave permanent disability. Dr Ewing recently, in Washington, struck a very true note when he stated that in most cases of recurrence the surgeon should realize his imperfect operative technique.

The present case is that of an undergraduate nurse, a patient of Dr Stevenson, who was quite able to do her work until March, 1924. At that time she complained of some pain and weakness in the right hip joint. The condition gradually became aggravated until she was obliged to go off duty and to lie up most of the time. At that time there was some tenderness of the joint, but she had full movement, the x-ray showed some rarefaction of the neck of the femur (Fig 1). The pain and weakness became more pronounced and an x-ray, taken in June, 1924, showed more rarefaction and a coxa vara condition (Fig 2). In August, 1924, when turning over in bed a pathological fracture of the neck of the femur was produced (Fig 3).

On December 23, 1924, I saw the patient and the problem naturally was to determine the cause of the fracture, whether it was fibrocystic disease or tumour. We were rather more inclined to believe that it was a giant-celled

* Read before the Montreal Medico-Chirurgical Society, April, 1928. Received for publication, August 16, 1928.

FIG 1

FIG 3

FIG 2

tumour. The operative problem was grave, as there was a marked loss of continuity in the neck of the femur, due to the extensive tumour involvement which left a mere shell with a fracture in the middle of the neck.

On December 26, 1924, the joint of the femur was exposed widely by the Smith-Peterson incision. The neck of the femur was found to consist of a soft shell from the acetabular rim well down to the trochanter, the fracture being felt about the middle of it. A flap of this shell was reflected and the contents were found to be

of the typical jelly-like consistency. This material was carefully spooned out and the lining was found to be smooth, except at each end. When it was swabbed out the cavity was left remarkably dry and practically no oozing was noted. The ilium was then exposed and a number of bone shivers were chiselled off and packed firmly into the cavity. One piece seemed to pierce through the shell into the acetabulum. The flap was then sutured in place, and the result was a fairly firm mass representing the neck of the femur. The wound was closed, and a long plaster spica applied.

There were no untoward symptoms after operation until about March, 1925, when Dr Stevenson found a swelling below the trochanter. This corresponded to an x-ray appearance which we had noted in December but had let alone, as we did not like to excavate the whole trochanter at the time. He exposed this swelling and carefully cleaned out the tumour and closed it up. This healed *per primam*. For eighteen months the patient was kept recumbent, and then fitted with a caliper walking brace. The bone seemed to regenerate firmly in the neck of the femur and below. I show an x-ray taken in June, 1927, which demonstrates strong bone and a moderate coxa vara (Fig 4).

Pathological examination of each specimen by Professor Oertel and Professor Rhea showed a typical giant-celled tumour (Fig 5).

The report in June, 1928, is that this patient walks with a slight limp, without pain, with full range of movement, and that she can

FIG 4

FIG 5

endure a full day's occupation. As this report is made three and a half years after operation we are encouraged in the belief of probable cure. I can offer no explanation for the vascularization of these pieces of autogenous bone-graft to form a firm supporting osseous structure replacing the original neck of the femur. The cavity in which they were placed at the time of operation seemed dry, and close inspection showed practically no oozing of blood into the cavity.

EMBOLISM OR THROMBOSIS OF THE CENTRAL RETINAL VESSELS?*

BY ANTONIO CANTERO, M.D., C.M.,

Quebec

The central artery and vein of the retina are both liable to be suddenly obstructed, and the result is sudden and usually complete loss of sight. The first case of this kind was seen by Graefe in 1858. Since that time somewhat similar cases have been reported, but when we find the retinal circulation suddenly obstructed we must use some care in making a differential diagnosis between embolism and thrombosis. The following case is of some interest, and may serve as an illustration.

A white male, 33 years of age, by occupation a steel worker, was admitted to the hospital complaining of sudden loss of the sight of the right eye and epistaxis.

Family History—Negative

Personal History—Denies having had any diseases of childhood, in 1915, pleurisy, in 1918, an attack of jaundice which lasted three weeks, in 1921, gonococcal infection. Lues was denied.

History of the Present Illness—Eight weeks previous to his admission the patient was returning home from church when he noticed a sudden loss of sight in the right eye. He described it as if a dark curtain was pulled suddenly down in front of the eye. He consulted someone who gave him thirty-eight ultra-violet treatments to the eye. Since then there has been total blindness of the eye, and there have been no signs of improvement.

Physical Examination—The patient was found to be suffering with a definite cardiac lesion, *i.e.*, mitral stenosis and aortic regurgitation, systolic blood pressure of 110, otherwise his other systems were negative. Urinalysis negative. Blood count red blood cells, 4,200,000 per c.mm., white blood cells, 4,400 per c.mm., haemoglobin, 78 per cent. Blood Wassermann test, 4 plus.

Ophthalmoscopic Examination—Left eye was normal. Right eye, a gray opacity, situated about the region of the macula and the optic disc.

* From the service of ophthalmology and otolaryngology, Jeffery Hale's Hospital.

was noted. There was a definite retinal haze. The fovea centralis could be made out, shining as a cherry-red spot. About its small vessels of the macula appeared and, though concealed in the opacity, they shone out in bright contrast to the white background. Pressure upon the globe evoked no pulsation of the arteries or veins.

By contrast, in thrombosis of the vein the arteries are diminished, but not empty and thready, the veins are of increased size, the nerve is whitest or is easily congested. Opacity in the retina, when it appears, develops quickly and may be very extensive, the fovea will have a bright red colour if the retina is opaque. Pressure may not cause pulsation, yet it has been produced in the veins. Vision is greatly reduced and may be destroyed, but eccentric sight sometimes remains, and improvement sometimes occurs.

SUMMARY

To recapitulate our findings (1) The sudden

and total loss of sight, with the absence of any improvement. (2) The definite cardiac lesion. (3) The classical ophthalmoscopic picture, *i.e.*, the arteries shrunken and the smaller ones invisible, veins reduced in size, especially at the optic nerve, the absence of retinal hæmorrhage, and the grayish white opacity about the region of the macula.

It should be noted that the milk-white opacity of the retina and the vivid redness of the fovea are common to many kinds of stoppage of the retinal circulation, and that too much stress should not be put upon the findings in making a differential diagnosis.

With the clinical history and ophthalmoscopic findings, the diagnosis of embolism of the central retinal artery is justified in the above case.

The prognosis is bad.

General treatment for his cardiac lesion was advised, with specific treatment for syphilis, *i.e.*, a full course of arsenic.

Diabetes of Ovarian Origin.—Carnot, Terris, and Caroli describe the case of a married woman, aged 36, in whom diabetes had not been relieved by anti-diabetic diet. The glycosuria amounted to approximately 100 grams daily, acetone and diacetic acid were sometimes present. The blood sugar was never more than 2 grams. The patient lost more than 22 pounds in weight in two months and became much weaker. Two preparations of insulin were administered with out result, except that diacetic acid disappeared from the urine. Prior to the first symptoms of diabetes menstruation was delayed, scanty, and finally absent, but before it ceased altogether it was noticed that the glycosuria increased a few days before the period. Apparently the ovarian endocrine action reduced the quantity of blood sugar. An ovarian extract was injected in doses of 1 ccm every second day. After the second injection a rapid fall in the glycosuria occurred, and the patient's ovarian pain disappeared. The general health improved rapidly, and the patient gained 11 pounds in ten days, menstruation reappeared normally after an absence of three months. The patient lost the saccharine taste in her mouth and her excessive hunger. Some days after the last injection of ovarian extract glycosuria increased, but it was reduced by a further series of hypodermic injections. The authors conclude that there is a close relationship between ovarian disturbances and diabetes, and that ovarian extract may reduce glycosuria and hyperglycæmia when insulin has failed.—*Brit M J*, 1928, ii, Epit 15.

Skin Eruptions with Phenobarbital (Luminal) —

The three cases reported by William C Menninger are the only cases in which the skin rash appeared in approximately four hundred cases in which phenobarbital has been used. From the data at hand, no relationship can be drawn between the amount of the drug and the weight of the patient. Phenobarbital may produce an urticarial reaction, or it may produce a scarlatina-like or morbilliform maculopapular erythema. In approximately 50 per cent of the reported cases of the latter condition there has been an associated pyrexia and other systemic toxic symptoms. In the face of the widespread usage of the drug, the number of cases showing such a toxic reaction must represent a very small percentage. A distinction should be made between the toxic reaction and the poison reaction. In the former, many of the cases do not show any particular relation to the dosage of the drug, and skin reactions have appeared frequently on small doses. It seems to Menninger that the cause must be a selective tissue reaction to the drug, dependent on constitutional factors about which we are still ignorant.—*J Am M Ass*, July 7, 1928.

An Early Conception of Wound-Infection.—"Upon the solution of Unity in any part of the ambient air repleted with various evaporations or aporrheas of mixt bodies, especially such as are then suffering the act of putrefaction, violently invadeth the part and thereupon impresseth an exotic miasm or noxious diathesis, which disposeth the blood successively arriving at the wound to putrefaction, by the intervention of fermentation." *Van Helmont* (1577-1644)

Clinical and Laboratory Notes

A SIMPLE APPARATUS FOR THE CONTINUOUS INTRAVENOUS ADMINISTRATION OF PHYSIOLOGICAL SALT SOLUTION

BY R I HARRIS, M B ,

AND

W O STODDART, M B

*Hospital for Sick Children
Toronto*

There are technical difficulties associated with the intravenous use of salt solution which make an improved method of administration desirable. The value of large amounts of fluid in the treatment of certain surgical conditions is universally conceded, but in those illnesses in which it is most valuable its administration by ordinary channels is often impossible. Under such circumstances, intravenous injection of salt solution is the most satisfactory method for the parenteral administration of fluid. To the intravenous injection of salt solution, as ordinarily practised, there are objections and limitations, and these difficulties are particularly great in children. If we consider intestinal obstruction as an example of a surgical condition in which the use of large amounts of fluid is a valuable form of treatment, it is evident that, to be of most value, the fluid must reach the circulation in quantities sufficient to compensate the large amounts lost by vomiting, and should be given at frequent intervals, or, better still, continuously, for the whole of the period in which the toxæmia of the obstruction is present. As ordinarily administered, the salt solution is injected into a vein once or twice daily. This intermittent administration is inadequate, since the need for the salt solution is continuous. It also limits the amount of fluid which can be given, since care must be taken to avoid overtaxing the heart. As a result, the amount of fluid given daily is apt to be less than the patient's requirements. In the case of children there are additional technical difficulties. It is rarely possible, except in the larger children, to introduce the fluid directly into the vein by puncture through the skin. In infants, it is true, the longitudinal sinus can be entered by a needle through the anterior fontanelle. In our opinion, the danger of intracranial hæmorrhage and of infection, though remote, is sufficiently great to make this route unsafe except as a last resort. To administer fluid intravenously to a child ordinarily necessitates the exposure of a superficial vein through a skin incision under local anæsthesia. Since each intravenous administration can only be accomplished by a minor operation, and as the need for salt solution ordinarily

extends over several days, several minor operations must be performed. The frequent repetition of this procedure is open to obvious objections: it is unnecessarily disturbing to the patient, the available veins are quickly used up, and several wounds are produced, each of which incurs the danger of infection. The natural desire to reduce to a minimum the frequency of the procedure leads to the administration of as large a quantity of fluid at one time as is judged safe. Under such circumstances, it is easy to overstep the margin of safety, and by the rapid administration of too large a quantity of fluid to overtax a feeble heart or failing circulation.

A consideration of these objections led us to the conclusion that the intravenous administration of salt solution would be greatly improved could the solution drip into the vein at a steady rate, but sufficiently slowly to permit its use for an indefinite period of time. Once started, the fluid could then be permitted to flow as long as the necessity for such treatment remained. The advantages of such a method are that the administration of the fluid is continuous, thus meeting the needs of the patient, large quantities can be given without overtaxing the patient's circulation, and it minimizes the amount of attention required. Certain technical difficulties must be met. The apparatus must be so constructed as to prevent contamination of the fluid by any organisms in the air. There must be means for determining the rate of flow. The rate of flow must be capable of ready adjustment. Care must be taken to avoid clotting in the cannula and infection in the wound.

We have succeeded in devising a piece of apparatus which fulfils these requirements and successfully permits the continuous administration of salt solution into veins for several days at a time. The apparatus has proved so satisfactory that we feel justified in publishing an account of it. The component parts are illustrated in Figure 1 with sufficient clearness to make detailed description unnecessary.

The technique of its use is simple. More than the usual aseptic care should be exercised, since the apparatus may be in use for several days. The receptacle for the fluid should be kept covered with a gauze and cotton filter. This should not be removed to renew the fluid, but, instead, a fresh flask should replace the empty one. By using large flasks (2,000 c.c. and 5,000 c.c. in capacity) they will not need replacing more than once daily. The small veins on the dorsum of the hand and foot are most convenient to use. Prior to preparing the vein, the wrist is fixed by a light anterior splint of cardboard or plaster. This permits the patient to move his arm about without disturbing the needle materially. Under local anæsthesia, a small transverse incision is

FIG 1—Diagram of the apparatus

The reservoir is made of pyrex glass in order to withstand the temperature of the autoclave in sterilization. The neck is capped with a gauze and cotton pad tied on. This is not removed as long as the flask is in use. When one flask is emptied it is replaced by a freshly sterilized full one. A hole drilled through the side of the bottle low down permits the insertion of a threaded metal tube which is held in place by nuts and rendered waterproof by rubber washers. The screw-cock permits regulation of the rate of flow. The glass capsule through which the fluid drips permits estimation of the rate of flow at any particular moment since the tip of the cannula in the capsule is of such a size that 20 drops from it equal 1 cubic centimetre.

FIG 2—Photograph of the apparatus in use

This picture shows the apparatus in use upon a patient suffering from intestinal obstruction following appendicitis. For more accurate delineation of details the dressings have been removed from the hand.

made over a vein, just large enough to accommodate a No. 17 gauge gold needle. The vein is ligated below, the cannula inserted through a small cut and tied in with catgut. A piece of sterile gauze is placed beneath the cannula to steady it and maintain it at a slight angle so that the opening in the needle will not be occluded by pressing against the side of the vein. The wound and needle are covered with a piece of sterile gauze and the whole secured by an encircling strip of adhesive tape. After connecting the rubber tubing to the needle, a pad is bandaged tightly over the whole, to protect and steady it.

There are a few points of importance, attention to which will facilitate the use of the apparatus. Glucose solutions should not be used. This substance in concentrated solutions produces thrombosis when injected into veins. This property is sufficiently marked to make glucose in 50 per cent solution one of the chemicals which are used in the injection treatment of varicose veins (¹). Even in the more dilute solutions (5 per cent and 10 per cent), which are so frequently used as intravenous medicaments, prolonged use will also result in thrombosis. As a routine, therefore, glucose solutions should not be given. If it is considered necessary to administer

glucose intravenously with this apparatus, the required amount should be given rapidly and be followed by physiological salt solution. Physiological salt solution, or Locke's solution, are the most satisfactory fluids for use in this apparatus. (Locke's solution consists of sodium chloride, 0.9 per cent, calcium chloride, 0.024 per cent, potassium chloride, 0.042 per cent, and sodium bicarbonate, 0.01 to 0.03 per cent. It contains all the saline elements of mammalian blood in their proper proportions.) Clotting in the needle gives little trouble if a small vein is used and if a steady flow is maintained. The rate of flow is readily adjusted by means of the screw pinch-cock, so that any quantity up from approximately 500 c.c. per twenty-four hours may be administered. The rate of flow at any particular moment is readily estimated. The nipple from which the fluid drips through the glass cannula is of such a size that twenty drops from its end equal one cubic centimetre. By counting the drops the rate of flow per minute is readily calculated.

No attempt is made to heat the fluid before it enters the vein. To be effective, the heat would require to be applied to the fluid immediately before it entered the vein, since the rate of flow of the fluid is so slow that were heat applied at

the reservoir much of it would be lost before the fluid entered the vein. To add to the apparatus an appliance for maintaining the fluid at body temperature would add greatly to its intricacy. In our opinion, it is simpler to heat the patient by means of hot water bottles than it is to heat the fluid. As a matter of experience we have found that the administration of fluid at room temperature by this method gives rise to no more disturbance than does the administration of fluid of similar temperature by mouth.

The advantages of the apparatus are sufficiently great to have established it in our hospital. By means of it we have been able to administer adequate amounts of fluid to surgical patients with a very small amount of attention. It has been used continuously for as long a period as ten days, without any interruption in the flow and without any difficulties associated with the wound. The ease with which fluids may be administered intravenously with its aid has permitted us to give larger amounts of fluid over longer periods of time than was formerly the case. This has caused so distinct an improvement in results that we are disposed to think that previously the amounts of fluid we were administering were much too small.

There is a limit beyond which the administration should not be pushed. This varies greatly in individual cases, depending upon the amount of dehydration present and upon the amount of vomiting which is occurring, we have formulated a rough rule that the amount of fluid administered should not exceed 35 c c for each pound of body weight in twenty-four hours.

While originally devised to meet the needs of certain surgical conditions, such as the toxæmia of intestinal obstruction and of burns, the apparatus has been found so useful that it is now used in nearly all the conditions met with in hospital practice in which parenteral administration of fluids will be required for twenty-four hours or longer.

The apparatus may be obtained from Ingram & Bell, and from J. F. Hartz & Co., Toronto.

Primary Sarcoma of Lower Lip—J. Vincent Fahs reviews fifteen cases already on record and reports one new case, occurring in a male, aged about 35, an ex-soldier and farmer, who had never served in the tropics and, aside from the usual diseases of childhood, had not had any illness of interest, though for a number of years he had had psoriasis. He stated that he had never had any venereal disease, and did not use alcohol and tobacco, no evidence of trauma to the lip could be elicited in his history. As a result of deep roentgen ray therapy and radium therapy, there was a decided decrease in size. However, six months later, roentgen ray examination of the chest revealed probable metastasis in the left lung. Death occurred shortly afterward. At the necropsy two

NORMAL RANGES FOR LABORATORY FINDINGS

By R. E. COLEMAN, M.B.

Vancouver

In response to a request we are here submitting a list of the "normal" ranges of body constituents as at present in use in the Vancouver General Hospital Laboratories. In using these the physician is reminded that the results of any laboratory analysis are but "a response to a technique," so that these "normals" are subject to changes of technique. For the same reason they may not be directly comparable in given instances with results from other laboratories.

Determination	Normal
Basal Metabolism	-10 to +15
Blood calcium, mg per 100 cc	10 to 11
Blood chlorides, mg per 100 cc	588 to 630
Blood creatinine, mg per 100 cc	1 to 2
Blood non-protein nitrogen, mg per 100 cc	25 to 35
Blood phosphorus, mg per 100 cc	3 to 4
Blood sugar, fasting, mg per 100 cc	80 to 110
Blood urea nitrogen, mg per 100 cc	12 to 15
Blood uric acid, mg per 100 cc	2 to 3.5
Spinal fluid, cells per cmm	0 to 5
Spinal fluid, chlorides, mg per 100 cc	725 to 740
Spinal fluid, sugar	about ½ blood sugar
Fragility	beginning at 0.44% complete at 0.36%
Phenolsulphonephthalein (P.S.P.) in two hours	60 to 85%
Red blood cells per cmm (men)	4,700,000 to 6,100,000
Red blood cells per cmm (women)	4,300,000 to 5,300,000
Hæmoglobin, per cmm (men)	83% to 106%
Hæmoglobin, per cmm (women)	71% to 92%
Colour index (men and women)	0.85 to 1.15
White cells per cmm	5,000 to 10,000
Platelets, per cmm	280,000 to 540,000

In the case of glucose curves, two hourly urine tests, and fat in the stools, the physician will find it more satisfactory to consult the laboratory staff since the normal range is not so easily expressed as are the above—*Bulletin of the Vancouver Medical Association*, 1928, iv, 286

nodules of new growth were found in the left lung—*J. Am. M. Ass.*, June 23, 1928

The Irradiation of Milk—Nearly two hundred delegates, representing forty-two countries, were present at the World Dairy Congress in London recently. During the proceedings it was shown that milk treated with ultra violet rays had proved its efficacy both as a preventive of rickets and as a cure. Dr. Wilhelm Hoffman, of Vienna, in a paper on "Activated Milk," said that from a prophylactic point of view the sale of a cheap activated milk to the masses was even more important than the direct treatment of the human body with artificial sunlight.—*Brit. J. Actinotherapy*, 1928, iii, 95

Editorial

THE INTERNATIONAL CONFERENCE ON CANCER A GENERAL SURVEY

THE first International Conference on Cancer, convened in London by The British Empire Cancer Campaign, an event of momentous importance, has come and gone. It is now in order to take stock of what has been accomplished. The "practical" man would doubtless say, "Very little." Yet this would be a most unfair and unfounded conclusion. It may be frankly admitted at the outset that we are still as far from a comprehension of the nature and cause of cancer as before. This is not to say, however, that no progress was made. It was surely a great gain that experts should have gathered from different countries, to record experiences, to exchange ideas, and to devise more comprehensive ways of attacking the problem of cancer control.

For more than thirty years the cancer problem has been studied, but mainly from the laboratory viewpoint, and the solution is not yet. It is no depreciation of the splendid contribution of the research workers to say that it is not sufficient, and that light must be sought in other directions also. This was one of the conclusions reached by the Conference. Such matters as the influence of heredity, locality, occupation, diet and race in the etiology of cancer need to be more fully studied, and this can only be done by the laborious accumulation and scientific analysis of facts and more facts. This task calls for the united and co-ordinated efforts of local investigators, central health authorities and international bodies, such as The British Empire Cancer Campaign and the Cancer Commission of the League of Nations.

The discussion on Etiology was opened by Professor James Ewing, of Cornell University, along general lines, and was participated in by many eminent authorities. The parasitic theory of cancer production found an able champion in Professor Borrel, but apparently received a mortal blow from the work of Dr. James B. Murphy and Professor

Archibald Leitch. The dramatic climax of the Conference was reached when Dr. Murphy, of the Rockefeller Institute, announced that, working with the Rous chicken sarcoma, he had been able to isolate a growth-producing substance which he regarded not as a virus but as something of the nature of an enzyme. This substance, which he had obtained and purified by fractional precipitation of the proteins in an extract of the chicken tumours, was capable, when injected, of producing tumours in fowls with great regularity. The agent in question was more resistant to the action of ultra-violet rays than were bacteria and viruses. Dr. Murphy thought it hardly conceivable that this active fraction, a substance purified by repeated precipitations, could carry with it through all the manipulations any living organisms or virus. The final and crucial proof, however, lay in the isolation of the same substance from material that certainly did not contain a virus. This he had been able to do. By a similar technique he had isolated from such normal tissues as the testes of normal fowls, which had not been in contact with any tumour-bearing animals, a similar substance with which he had produced the typical tumour, transplantable in more than ninety per cent of fowls. The work of Professor Leitch, of the Cancer Hospital, London, on the Rous tumour, carried out independently, tended to confirm Dr. Murphy's conclusions.

These remarkable observations, while they do not solve the riddle of malignancy, yet probably indicate an advance in our knowledge, and open up a new biological problem of far-reaching significance. The prospect is alluring, but more work along these lines is called for before the final appraisal of the findings of Murphy and Leitch can be made.

On the engrossing subject of the value of lead in the treatment of malignant disease Professor W. Blair Bell, of Liverpool, read a paper entitled, "Chemotherapy in Malignant Disease" (*Lancet*, 1928, ii, 164) in which

he states his opinions very temperately. He believes that "there is a considerable body of evidence supporting the view that by itself lead, even in the crude preparations now used, can cause the disappearance and apparent cure of malignant neoplasms in favourable circumstances, and can sometimes beneficially affect leukaemia and other neoplastic conditions." Professor Bell also felt that the effects of radiation were augmented by the previous use of lead, and that the employment of lead as a prophylactic measure against recurrence after surgical operations for cancer will be held to be of great value. The discussion that followed was summarized by the Chairman Sir

Thomas Horder, when he said that it must be admitted that some patients have got well after treatment with lead and as a result of it. At the same time, the method was not so safe that physicians should assume the responsibility of advising their patients to submit to it, and that further research should be undertaken for lead preparations less toxic than those now in use, in the hope of widening the margin of safety at present dangerously small.

Perhaps the most immediately fruitful outcome of the Conference was the agreement of the members that radium was a valuable adjunct to surgery, and in certain cases had proved to be an efficient substitute for it.

RADIUM THERAPY IN CANCER

IT is difficult to completely appraise the results of the recent International Conference on Cancer, beyond saying that it has helped to co-ordinate our existing knowledge of cancer. This was stated in advance to be one of the purposes of the Conference, and appreciation of its value from this point of view was well expressed in the opening address by His Majesty the King when he said that if the discussions led to advance in diagnosis, treatment, or even palliation of the disease, the Conference would have justified itself and earned the gratitude of mankind.

The full benefit of this assimilation of knowledge belongs, however, to the future, for we still have not solved the vitally important problems of the causation of tumours and the nature of their growth, but there is one aspect of the cancer question, whose growing importance was emphasized by discussions at the congress, namely, the value of radium in comparison with surgery in the treatment of certain types and at certain stages of cancer.

The use of radium has now passed well beyond the experimental stage. Not only has research increased our understanding of the physics of the element, and consequently its therapeutic applications, but enough time has elapsed since its first employment to allow some estimate to be formed regarding its ultimate effects. We know, for example, that tumours vary considerably in their

sensitivity to radiation. Epitheliomata of the epidermis and of the oral region are specially sensitive, and their cure by radium may now be predicted with confidence. Cancers of the breast and of the cervix uteri are likewise sensitive to radiation, but treatment of these may be complicated by the degree of extension to deeper structures. On the other hand, rectal cancer is distinctly resistant to radiation, and adenocarcinomata of the uterus as well as that of other glands are likewise only slightly affected by radium.

If, however, research has defined the limitations of radium treatment there is conclusive evidence to demonstrate its value within those limits. There are now available for reference collected statistics whose analysis shows that the end results of radium treatment in the types of cancer mentioned, are, broadly speaking, as successful as those produced by surgical methods. This evidence is particularly plentiful in the case of cancer of the cervix uteri, one of the most exhaustive reports being that prepared by Dr Janet Claypon, based on data published in sixteen different countries, and relating to records in about 80,000 cases treated by radium or surgery (Pub. Min. of Health, 1927, xl). Heyman, of Stockholm, (*Acta Radiol.*, 1927, viii, 3637) has also published statistics along these lines from twenty surgical and seventeen radiological clinics in Europe and America.

In such cases, therefore, radium can be said to show at least as good results as surgery, but there are other considerations to be taken into account. There is, for example, no "operative mortality" from the use of radium, that is, a patient may be considered an entirely favourable operative risk, and yet in a large series operation produces a definite mortality percentage which is practically absent when radium is used, and, in addition, there is a small but definite proportion of cases classed as inoperable which have been successfully treated by radium.

It may be accepted, therefore, that, with certain qualifications, radium and surgery are equally effective in dealing with cancer, whilst in combination they may serve to considerably augment each other's scope. There is little doubt, also, that if it were more generally known that surgery is not the only treatment for cancer, there would be less hesitation amongst the laity in seeking medical advice at earlier stages of the disease, which is an essential condition for success with any treatment.

The chief difficulty in the use of radium is

the expense. It has been estimated that the cost of a quantity large enough to supply the probable needs each year in a country like Great Britain would be somewhere in the neighbourhood of a million dollars. This element of expense, together with the highly specialized technique required for its employment, brings the matter, as Sir Geo Buchanan has pointed out (*Lancet*, 1928, ii, 160), into the sphere of "public action," but even if this (not necessarily ideal) solution is not reached, there is still a very strong case for organized centralization. So far, radium treatment has been developed chiefly by the efforts of individual workers, carrying out observations on clinical results, but Professor Claud Regaud, the head of the first Radium Institute in the world, in the country in which radium was discovered, said at the Conference that he thought it would be a mistake to increase the number of centres for radium research, but that these should, as far as possible, be centralized. This is a matter which will depend to some extent on local conditions, but at present it would seem wise to develop a few centres to their fullest extent.

IS STATE MEDICINE IN THE OFFING?

CONSIDERABLE concern has, in the last four or five years, been shown in the United States on the subject of the growing scarcity of medical practitioners in the rural portions of the Union and also on the high cost of medical service in the cities.

Evidence of this concern was given in a communication from the National Grange, an organization that includes 800,000 members who are engaged in agricultural pursuits, addressed to the American Medical Association, and read at its meeting in Minneapolis on June the 11th. In this communication the Grange pointed out the ever-increasing scarcity of physicians in the small towns and rural sections in the Union. There were in 1906, it says, 33,000 in places of 1,000 inhabitants or less, but in 1926 the number had fallen to 27,000 and, further, one-third of the towns of 1,000 or less, throughout the United States, which had physicians in 1914, had none in 1925. From the fact that the

average age of death of physicians is 62, while the average age of rural doctors throughout the Union in 1925 was 52, it is predicted that the present generation of country doctors will have practically disappeared in another ten years. That the country doctor will disappear in a few years seems to be indicated also by the fact that only a very small percentage of those who have graduated in the last ten years have taken up the practice of their profession in rural districts, and as a result there are many scores of rural counties where not a single doctor who has received his degree since 1918 has settled. In consequence there are increasing hosts in the rural sections who are "medically helpless, while the cost of medical service, where it is to be had, mounts higher and higher."

That no relief for this situation will come from an increase in the number of those annually graduating as doctors is clear

The Commission on Medical Education has reported that the number of physicians in practice is actually decreasing, and that the number will not regain its present size, 130,000, until 1965. In the meantime the population of the country, the Commission estimates, will have increased from 115 millions to 165 millions.

One reason given for this decrease is, in the words of a Committee reporting last year at the Washington meeting of the American Medical Association, that "the medical profession does not attract so many qualified young men and women as formerly." This Committee also noted that a dangerous concentration of doctors in cities is taking place, leaving the rural communities without adequate medical service.

The National Grange believes that the cause of this growing scarcity is due to the greatly increased requirements for graduation, the increase from four to seven years to complete the curriculum, and the cost of a medical training \$7,000 to \$8,000 which must be borne by a young man, twenty-five or thirty years old, who, according to Dr. W. A. Pusey, a former President of the American Medical Association, "is not looking for an ordinary practice among ordinary people in the cities, or for any practice in the country."

The National Grange would change all this. It does not advocate a lowering of the standards, but more practical instruction, which may be acquired in less time and with the expenditure of less money than under prevailing conditions. It quotes the opinion of many physicians of the highest standing "that present medical education is not giving the most resourceful practitioners for ordinary service, it is producing practitioners who are dependent on hospitals and laboratories, while these facilities, according to authoritative medical opinions, are necessary in hardly more than ten per cent of illnesses and accidents." For the care of ninety per cent of the illnesses and accidents in rural sections independent resourceful physicians are needed. This ninety per cent of illnesses cannot be handled through distant doctors and hospitals. The National Grange believes that a proper medical training can be given a student in four years after he leaves the High School, instead of in the seven years now required.

The problem, according to the National Grange, must be solved by the medical profession. There has been, in the last twenty years, a decrease in the number of medical schools in the United States from 160 to 69. Many of those forced out of existence did useful service, while of those which remain nearly all receive large appropriations of public funds, but the direction and control of such has passed out of the hands of the people or their representatives. If the profession fails to remedy this situation, "it is for the people to determine whether it would not be good policy, as necessity demands, for the States to build and maintain medical schools solely under public control and responsive to the needs of humanity."

The response of the delegates to this communication from the National Grange was non-committal. In the discussion of it some of the delegates admitted the urgency of the need of more rural practitioners, but others maintained that the situation was not as serious as it was represented, and that there had been some improvement in it in the last few years, while another claimed that the problem is an economic one, but that it is true that the present system of medical education tends to specialization on the part of the profession and that it is difficult to induce the recent graduate to practice in a rural community, because he is instinctively tinctured with the idea that progress, that achievement, that personal advancement, can only be obtained through the medium of specialization or location in larger cities.

The Committee on Medical Education, which reported at this meeting of the Association, referred to the unrest with regard to rural medical service, to the expensiveness of medical service in general, and to the strong criticism directed at medical education from all quarters. It recommended that medical students should graduate and enter practice at an earlier age than at present, and that the medical course be reduced from four years of three quarters each to three years of four quarters each, and it expressed the opinion that the medical course is overcrowded with details and with detailed consideration of the specialties, and that it would be improved if it were much less crowded and more con-

finer to the essentials and the fundamentals. This report was unanimously adopted by the delegates!

In the discussion one of the delegates stated that the problem in this question is close to the heart of every one who is opposed to State Medicine, and another expressed the fear that one of the suggested solutions of the rural situation would lead to contract practice and incidentally put the stamp of approval on State Medicine.

In other quarters concern at the cost of medical service has been shown. A writer in the *Atlantic Monthly*, more than a year ago, dealt with this subject and pointed out that cases of midwifery in very moderately well-to-do circles now cost \$500.00, whereas twenty to thirty years ago they did not involve more than \$50.00. Dr. Wilbur, President of the Leland Stanford University, a medical graduate, impressed with the urgency of this subject, has organized a Committee on the Cost of Medical Care, to study and report on it. In a letter to the *Journal of the American Medical Association* which appears in the issue of June 30, he explains the reason for his action and refers to the widespread dissatisfaction of the public with the existing

situation in medicine, in doing so quoting from the *Journal of the Michigan State Medical Society* of 1922: "The tendency of the day is that where any group of citizens cannot afford to purchase certain privileges, services, or needed comforts, the demand goes forth that the State supply to them that which they cannot now obtain. The State and County usually comply with pressing demands of its citizens. We are fearful that we are on the eve of such a demand from the people. What are you going to do about it?"

Dr. Wilbur remarks that in the same year the President of the Ohio State Medical Association made a similar statement and asked a similar question, and that there have been in the last ten years many warnings like these, but the medical organizations have done little in regard to the problem, and that is why his Committee was organized.

It is evident that the situation in the United States is serious. Is State Medicine in the offing? What will the effect be ultimately on the status of the medical profession in Canada?

A. B. MACCALLUM

THE COST OF MEDICAL CARE

SOME months ago reference was made in these columns to a meeting held at Washington, at which it was decided to establish a committee to investigate the cost of medical care. This committee has now been formed with a total personnel of forty-two members. The Chairman of the committee is Dr. Ray Lyman Wilbur, President of Stanford University, and one of the few medical men to reach the distinction of appointment to the presidency of a large university.

Of Dr. Wilbur's Committee, slightly more than half hold medical degrees, and these represent various types of medical activity. Fourteen are private practitioners, while nine represent public health services. The remaining nineteen include eminent economists, representatives of various medical institutions and organizations, and a number who may be described as representatives of the

general public. Dr. Winslow, Professor of Public Health at Yale is Vice-Chairman of the committee, and Chairman of the Executive. Harry H. Moore, Ph.D., of Washington, has been chosen as Director of Study.

A number of institutions which are interested in health problems have subscribed liberally to the support of the program, which will be carried on over a period of five years. For the first year it is expected that the expenditure will amount to sixty thousand dollars, while for succeeding years not less than seventy-five thousand dollars will be required annually.

The committee has recently issued a booklet describing its proposed activities, and from time to time journal articles will be published reporting upon various phases of the committee's researches. The ultimate question to be faced is how can practitioners'

equipment and technique, required in modern medicine, be utilized for the most efficient production of service. How can general practitioners and specialists, laboratory services, and various types of therapy, be most effectively organized into unit agencies? And how can unit agencies and services, both private and public, be best co-ordinated into a well balanced program of preventive and curative medicine? It is, however, felt that this ultimate question cannot be dealt with until the fundamental facts are made available. The present program of the committee is therefore limited to three groups of studies

- 1 Preliminary surveys of data showing the incidence of disease and disability requiring medical services, and of generally existing facilities for dealing with them,

- 2 Studies on the cost to the family for medical services, and the return accruing to the physician and other agents furnishing such services,

- 3 Analysis of especially organized facilities for medical care now serving particular groups of the population

The cost of medical care has been giving concern to members of the medical profession for several decades. We have realized for years that the poor man and the rich man are on practically an equal footing, so far as getting the best of medical attention is concerned, but that the man of moderate means is not able to afford the various tests made in the x-ray and other laboratories which have become so notable a feature of present day medical practise. We have hitched uneasily as we have made out accounts in which our own services have been rated more highly than in former years, and have endeavoured to excuse ourselves because the medical course has been lengthened and made more expensive. We have felt genuinely worried when it has been necessary to send patients to hospital who have refused to enter other than the private wards, and when it has been necessary to insist on the employment of a trained nurse in the home, or of a "special" in the hospital, conscience has troubled us greatly. We have realized that the modern disposition to prescribe the newer, and particularly the synthetic, drugs has added materially to the

bills for medicines. So we are not unaware that the cost of medical care has been increasing rapidly, and that it has, in fact, become a serious burden to people of moderate incomes. To a certain extent only does it lie in our power to bring about any reform in the situation. We cannot control hospital fees, and nurses' fees. We can have little control over the fees of laboratory specialists, and our own fees must be such as to enable us to live. It is, therefore, rather disappointing to learn that the committee on the cost of medical care will not give particular attention to means by which the cost of medical care can be reduced. The committee has laid down a list of seventeen different subjects which it proposes either to study itself or to have some agency like the United States Public Health Service study for it. There can be no doubt that as a result of these studies we will have more exact knowledge than we now possess, but it is difficult to escape the doubt whether this will help us very much. We will almost certainly learn that all the blame for the increased cost of medical care cannot be laid upon physicians, but that a very considerable share of it is really attributable to those who complain most bitterly, persons whose incomes may be very moderate but who in case of illness will be satisfied only with what they regard to be the best of hospital accommodation and of medical and nursing care. The lady who got along comfortably a few years ago with fifty-cent cashmere stockings cannot to-day satisfy herself with anything but silk stockings at several dollars a pair, and must also have a motor car.

A very casual inspection of shop windows shows that it is not merely the cost of medical care which has advanced within recent years. We must pay more even for our corned beef and cabbage than we did a few years ago. The problem to which the committee has set itself thus has many angles, and it is not unlikely that the studies which have at present been set down will increase in number and perhaps may even closely approximate the number of varieties of food stuffs which a certain concern saves us the trouble of preparing. We may feel then that the committee has a large and difficult task. Just how useful its efforts may prove the future

alone can disclose, but the personnel of the committee leads us to believe that its deliberations will be safe and sane, and that

much that will be of practical use will come out of its studies

W. H. HATTE

THE CHEMICAL NATURE OF INSULIN

THE most definite means of ensuring chemical purity of a compound is its production in crystalline form. Three internal secretions have so far been so obtained, adrenine, thyroxine, and insulin. Adrenine, $C_9H_{13}NO_3$, with a molecular weight of 183, and thyroxine, $C_{15}H_{11}NO_4I_4$, with a molecular weight of 523 (65 per cent of which is due to four atoms of iodine), have, compared with starch, glycogen, and proteins, relatively small molecules. It is customary to consider that most of the internal secretions have such relatively small molecules. This would account for their easy passage through animal cellular membranes.

Until recently the most highly active insulin preparations were still amorphous in character. Investigators were forced to the conclusion that they were complex in character, corresponding to the protein derivatives termed proteoses. In 1926 Abel announced the preparation of insulin in crystalline form. Pyridine was used as the agent essential for the precipitation of impurities. Abel and his collaborators¹ prepared 0.53 gram of crystalline (rhombohedral) insulin from two grams of a commercial preparation evaluated at 13 international rabbit units per milligram. This gives some idea of the degree of purity of such solid amorphous preparations. The rabbit value of the crystals is at least 40, and possibly 60, units per milligram. That is, or e-fortieth (perhaps one-sixtieth) of a milligram of pure insulin per kilogram rabbit is sufficient to produce hypoglycæmic convulsions in this animal.

Abel and his colleagues, assuming that one sulphur atom is present in the molecule of insulin, obtained the empirical formula $C_{45}H_{75}O_{17}N_{11}S$, while du Vigneaud², working in Murlin's laboratory, proved that the disulphide linkage of cystine ($-S-S-$) must be present, whence the empirical formula must be at least $C_{90}H_{150}O_{34}N_{22}S_2$. This corresponds to a molecular weight of 2,146.

Three recent papers from Abel's laboratory

by du Vigneaud, Jensen, and Winter steiner^{3, 4, 5} have amplified, but by no means completed, our knowledge of the chemical nature of the insulin molecule. They have shown that hydrolysed insulin crystals yield 8 per cent of cystine, 12 per cent of tryosine, 4.4 per cent of histidine, 3.2 per cent of arginine, and 2.26 per cent of lysine. The total nitrogen, 15.6 per cent, and the amino-nitrogen, 12 per cent, are in agreement with the supposition that the insulin molecule is completely or almost completely, built up from amino-acid radicals, so that the residual 70 per cent must consist in large part of radicals of the simpler amino-acids. Tryptophane is absent. The radical of a second sulphur compound appears to be present.

Assuming the correctness of these figures, the 8 per cent of cystine represents a molecular weight of the order of 2700, if but one cystine radical be present, while if 4.4 per cent represents one radical of histidine the weight of the molecule would be more than 3500. In all probability the molecule is therefore at least twice as large as du Vigneaud's first estimate. It is certain that the molecule of insulin is vastly more complex than those of adrenine and thyroxine, and that insulin itself must possess the general properties of a proteose.

In view of the importance that cystine and the cystine derivative glutathione have been shown to play in metabolic processes involving oxidation, it is interesting to speculate whether the cystine radical of insulin plays some similar rôle in the functioning of that compound. Although the clinical preparations of insulin adequately meet therapeutic needs, the wider knowledge of the compound that is now being acquired may lead, through better understanding of its mode of action, to even better and more systematic methods of treatment of pathological carbohydrate metabolism.

POST-GRADUATE COURSES IN ENGLISH AT PARIS

An innovation of much importance is about to be initiated in Paris by the Association for the Development of Medical Relations between France and Allied Countries, under the auspices of the Dean and the Medical Faculty of Paris. It is the establishment of a course of lectures and demonstrations in English in medicine, surgery, paediatrics, ophthalmology, oto-laryngology, morbid anatomy, and operative work on animals and the cadaver. Some of the most prominent clinical men in Paris will collaborate with their assistants in conducting this course, such as Professors Emile Sergent, Antonin Clerc, Armand Delille, Weill-Hallé, Antonin Gosset, Morax, and Lemaitre.

All are aware of the great prominence that Germany and Austria attained before the War in the matter of post-graduate courses in medicine. Vienna and Berlin attracted perhaps most of the English-speaking physicians from this side of the water, on account of their enormous clinical material, and the excellent systematized courses of instruction that were offered. Some of these courses were conducted in English. As a result, German ideals in medicine and German ideas in therapeutics were disseminated widely throughout Canada and the United States. While our French-Canadian confrères have always looked to Paris for their inspiration, the English-speaking physicians rarely did. Possibly, another reason for the attractiveness of the German schools lay in the fact that it was impossible for English-speaking physicians to get the same quality of work in the same space of time in England, where they would, naturally, have preferred to go. Now, however, things are improved. Post-graduate work of the highest quality can be obtained in England, under more favourable conditions than formerly, and there is less inducement to go to foreign countries. Nevertheless, it is of much advantage to get the points of view of our medical colleagues in foreign countries, and, therefore, we, in Canada, welcome this, the first serious attempt to interest English-speaking physicians in French clinical methods. Those of us living in the Province of Quebec, side by side with the French-speaking Canadians, are particularly interested in this movement to draw French and English medical men together. We wish it all

success. Our special thanks are due to Dr J. E. Dubé, Professor of Clinical Medicine in the University of Montreal, whose efforts, extending over the past two years, have at last been crowned with success, and to our contemporary *L'Union Médicale du Canada*, for its powerful aid.

The course in Paris will be given during the month of October, and the salient features of the program offered will be found elsewhere in this issue, (under "General News").

If we have any word of criticism it is that we doubt whether the month of October is the best time to stage this attractive curriculum. The university teachers, at least, will be greatly occupied at that time with planning their winter's work, and the practising physicians will have already taken their holidays, and will probably not wish to be away from home a second time. It is proposed, we understand, that the post-graduate course at Paris in English will be made an annual affair, if the first effort proves attractive enough. A better time than October, in our judgment, would be in summer or early spring. This is an important matter, as the success and continuation of the venture will in large part depend upon the attendance. The movement is a friendly gesture and is cordially commended to our readers.

BACTERIOPHAGE AS A FILTERABLE VIRUS

The above was the title of a paper read by Bronfenbrenner¹ before the New York Pathological Society in December.

The idea may at first seem novel, even revolutionary, yet Rivers² in his review of the subject of filterable viruses places bacteriophage first in his long table of known viruses and in fact thinks it is the best example of a filterable virus we know. This need not necessarily lead to the interpretation that bacteriophage is a living agent, as Rivers again is still undecided whether filterable viruses are living and certainly the clinching experiment proving this has yet to be done.

The most plausible explanation of the bacteriophage phenomenon is that suggested by Bronfenbrenner who thinks it is a metabolite produced during bacterial growth which stimulates the

micro-organisms This stimulation leads to accumulation of products in the cell and consequent water imbibition, the cell wall then rupturing from intracellular tension In other words bacteriophage may crudely be compared with such a cellular metabolite as carbon dioxide which is a stimulant in low concentration The essential property of bacteriophage is thus not *a priori* its property of destroying the cell, which is secondary, but its specific stimulating effect

Bacteriophage and the filterable viruses (the latter term being used here in its usually accepted narrow sense of those which attack plants, animals or man, with the following properties in common, *viz*, that they are filterable and invisible to ordinary microscopic vision, and have never been grown outside a living cell) both exhibit a marked specificity and the pathological changes produced by them are essentially the same Bronfenbrenner, by means of cinematographic films, has demonstrated the sequence of events taking place when bacteria are exposed to bacteriophage The micro-organisms first reproduce rapidly and increase abnormally in number, they then swell and rupture, the contents being extruded This is in essence the intracellular pathological change which Rivers has depicted in the case of the virus diseases of plants and animals The affected cells proliferate, increase greatly in size, then degenerate, and a vesicle is formed

It seems safe to assume then that the bacteriophage is a filterable virus, whatever this may be, and the whole chain of living cells which may be affected by these agents is now complete, from the lowest known unicellular plant cells, bacteria, up the scale to plants, insects, fish, birds, mammals and man

Perhaps these agents are after all "the intermediate form between life and death," as suggested by Professor Boycott in his address at the opening of the Pathological Institute at McGill University some years ago

ARNOLD BRANCH

THE "TENNIS ELBOW"

Some little interest has been taken recently in the medical and surgical aspects of sport In a former number of this *Journal* (1927, xvii, 1324) there appeared an article by Drs L J Austin, and W A Campbell, of Kingston, on injuries of the knee due to playing football, and in the *British Medical Journal* (1928, i, 12), is one by

Mr G Percival Mills on the treatment of "Tennis Elbow" Quite recently, too, a considerable volume, covering the whole gamut of sport, has been produced by a German scientist, whose name has escaped us, dealing with the subject with German thoroughness

It may not be inappropriate, now that the days consecrated to sport are upon us, to consider the condition termed by Mr Mills "Tennis Elbow" This is a condition almost confined to tennis-players, golfers, and those who must constantly wield a hammer It comes on insidiously and there is seldom any history of accident or sudden strain The person affected can usually perform any movement with his arm without pain except one, which invariably causes pain During the acute stage the patient will often drop a teacup when reaching forward to take it off a tray This is often diagnostic A tender spot can usually be recognized just above or below the external epicondyle, and the pain can often be elicited by complete flexion of the wrist and fingers Mr Mills adopted the following procedure with success Under nitrous oxide anaesthesia, he flexed the wrist and fingers, fully pronated the forearm, and then forced the elbow into hyperextension, at the same time making firm pressure over the tender spot by the external condyle There may be heard a click or snap, or even a loud noise, under this manipulation, though often the snap can only be felt

In chronic cases part of the trouble may be due to adhesions, but it is hard to resist the conclusion, in the acute cases certainly, that something is out of place It is suggested that in acute cases a portion of the orbicular ligament may slip between the head of the radius and the capitellum

BIBLIOTHECA OSLERIANA

We have received word that efforts are being made to ship the Osler Library to Montreal before navigation closes Arrangements for the packing of it will commence early in September It is doubtful however if the catalogue will be ready by that date, but it is hoped that it may appear before the end of the year This catalogue is to a large extent annotated bio-bibliographically Many of the notes were made by Sir William Osler himself Seven hundred and fifty copies of the catalogue will be on sale We hope in our next issue to present our readers with a more detailed account of this most interesting library

ERRATUM

The footnote to the editorial on p 216 of the August issue should have read "Dr H H Murphy," instead of "Dr G H Murphy"

REPORT OF THE BRITISH COMMITTEE ON VACCINATION

The report of the committee appointed by the Minister of Health in Great Britain, in conjunction with the Medical Research Council, in February, 1926, to investigate certain problems which have arisen in connection with vaccination, is just issued¹. In it the committee reports on details of the preparation, testing and standardization of the lymph, as well as on the means taken to ensure its purity and freedom from other germs which might do harm and the most desirable and efficient method for performing the operation is discussed. An abstract of the report is herewith presented.

The lymph used at present in England for vaccination is prepared at the Government lymph establishment. The seed lymph employed there was derived from calf lymph received from Cologne in 1907, and its quality has been maintained by cutaneous passage through the rabbit. Transference from calf to calf was found to lead to deterioration in the lymph and unsatisfactory vesiculation. The report emphasizes the desirability of discovering some method of producing lymph absolutely free from extraneous organisms. Carrel and Rivers have shown that the vaccine virus proliferates when grown *in vitro* in contact with chick embryo cells, and that by this method the potency of the virus is greatly enhanced. It has also been found possible to inoculate rabbits by the intracerebellar route, and it is claimed that the product yielded is very considerable and suitable for human vaccination. Lymph produced by either of these processes it is claimed would be free from any contaminating organisms.

Experience shows us that, notwithstanding the great value of vaccination, certain risks do occur, though their percentage is very small. Certain recommendations made by the commission appointed, in 1889, to investigate the cause of these accidental occurrences made the following changes in their instructions—The age period for vaccination was extended to six months after birth, certain technical regulations were advised to ensure cleanliness and the avoidance of sepsis and erysipelas, tubes were recommended to be used instead of dry points, and the vaccinator was directed to render medical attendance in case of any illness supervening if asked to do so by the parent. As the result of these new instructions, a reduction in the number of fatalities following vaccination was immediately noticed. In the five-year period 1886 to 1891 in which 4,290,000 infants were vaccinated, there were 279 deaths at all ages. During the fifteen years from 1910 to 1925, 5,500,000 infants were vac-

inated, with only 128 deaths. The present report suggests that the system of inspecting the patient on the seventh day is not desirable, an inspection should be made at some time during the second week, and a second inspection should be obligatory in the third week. It recommends that the principle of stational vaccination be adopted instead of the present system of domiciliary vaccination, and states that careful investigations made do not afford any evidence that vaccinia increases the liability to disease, either general or specific, nor does it appear to aggravate a disease already established.

In 1922, a few cases were reported in the medical press in which it was stated that a fatal encephalitis appeared to have developed as a sequence of a recent vaccination. In the following year, a larger number of cases occurred in which death was said to have been due to an attack of encephalitis following a recent vaccination. Investigation of these cases by a special committee showed that 11 cases occurred in London in the autumn of 1922, and a second group of 49 cases occurred in the summer of 1923, chiefly in provincial districts. Extensive investigations regarding these brought out the fact that the number of cases of post-vaccinal encephalitis bore no direct relation to the number of persons vaccinated, although there appeared to be an undoubted association in time between the post-vaccinal cases of encephalitis and the prevalence of vaccination throughout the country generally, charts showed, however, that the period of 1923, during which the majority of post-vaccinal cases occurred, was immediately antecedent to the development of an epidemic of poliomyelitis and polioencephalitis throughout the country. The committee expressed the opinion that it appeared extremely improbable that the cases could have been due solely to the vaccine virus, it was conceivable that a virus, such as that of poliomyelitis, which could only occasionally set up encephalitis in an individual in normal health, might, if another virus such as that of vaccinia was present in the brain, be enabled to do so. Evidence was not sufficient to declare the vaccine virus to be the sole cause of the disease, but the committee, after their investigation, considered that it was probable that the co-operation of some other organism besides that of the vaccinia existed in these fatal cases. Furthermore, it was stated that a condition similar to post-vaccinal encephalitis has occurred independently of recent vaccination or of the development of any observed exanthemata †.

† Recent reports in the daily press state that the League of Nations' Health Committee has received information regarding the increasing frequency of the development of encephalitis lethargica after vaccination. The situation has become so bad in the Netherlands that compulsory vaccination in the public schools is said to have been suspended for a year.

¹Report of Committee on Vaccination. H. M. Stationery Office, pp 303, 18 appendices with charts, 7s net.

The efficiency of the various methods of vaccination in producing complete immunity was investigated by Dr A F Cameron and Dr Brownlee at the beginning of the present century. Dr Cameron's conclusions were that protection against a fatal issue in an attack of smallpox was directly related to the number of scars and to the area of the cicatrix, and for all practical purposes the period of effective immunity may be regarded as not less than seven years.

The mild type of smallpox which has prevailed in Great Britain for the past five years has been benign, with an almost negligible mortality. As a result there has arisen a marked disinclination to submit to adult vaccination. It is affirmed that vaccination is worse than the disease, and that it is commonly possible to continue at work with little or no discomfort during an attack of this mild form, whereas abstention from work is generally necessary after vaccination. Owing to this fact, and in order to render vaccination acceptable without impairing its efficiency, the committee recommends that an effort should be made to reduce to a minimum the amount of trauma inflicted in vaccination. It considers that it is possible to secure success by a technique consisting of the infliction of a single linear incision, not more than one-fourth of an inch in length and strictly limited to the epidermis. If in this way we ascertain the smallest amount of virus sufficient to produce immunity it might be found possible to produce a vaccine which would cause less local and less general reaction than now frequently results.

ACCIDENTAL FATALITIES FROM INJECTIONS OF SERUM

By H E MACDERMOT, M D,
Assistant Editor
Montreal

There is more than one recorded instance of fatal results attending the administration of diphtheria toxin-antitoxin. In one series of cases at Baden, in 1923, the pure toxin was given by mistake, in another series at Dallas, Texas, there was an error in the mixing of the toxin with the antitoxin, in yet another, at Bridgewater and Concord, Mass., the toxin-antitoxin had been frozen and thawed before use, with consequent destruction of the antitoxin fraction. The investigations into these accidents clearly showed how they came about, and the results in each instance were such as might have been expected under the circumstances, but the latest occurrence of the kind in Australia presents somewhat unusual aspects. The events in brief were as follows*.

The public health authorities of Queensland had instituted a course of active immunization against diphtheria by the accepted method of

inoculation with toxin-antitoxin, and the work was begun in the city of Bundaberg by the local medical officer of health, in January, 1928. The serum used was prepared by the Commonwealth Serum Laboratories, Melbourne, and was distributed generally throughout the State. Its preparation had been in accordance with accepted methods, but for certain reasons it was decided not to add any antiseptic. To offset this, however, it was at first arranged to issue it only in sealed glass ampoules, each one of which would be a single dose, but later on the serum was sent out in rubber-capped bottles containing enough for several doses thus involving the withdrawal of the material from the same bottle several times. A warning as to the absence of antiseptic in the bottles and the possibility of contamination of their contents by repeated withdrawal was issued, but was not given sufficient publicity, at all events, the information did not reach the medical officer at Bundaberg.

In the course of ten days a total of 31 children in Bundaberg were inoculated from the one bottle of serum, and at first nothing unusual was noted. But on January 27th, of 21 children who received toxin-antitoxin (13 of them for the first time, and 8 for the second time) 12 became violently ill within five to seven hours, and died in from fifteen to thirty-four hours, 6 developed severe but not fatal symptoms, and 3 remained perfectly well. The ages varied from one year and three months to nine and a half years.

In the subsequent inquiry by a Royal Commission there was some difficulty in collecting the precise information necessary to explain what had taken place. The clinical study of the cases had been admittedly incomplete. The blood had not been examined, there were no notes on the condition of the nervous system, no urinalyses had been performed, even the actual descriptions of the symptoms were vague and in some cases inexact. It is pointed out by the Commission that these defects were the consequence of local conditions which made it virtually impossible to do any more than was done to deal with the emergency. The facts as finally established, however, showed that in the fatal cases the symptoms had been sudden and overwhelming. They were practically the same in each, vomiting at the outset, soon followed by diarrhoea, but with no blood in the stool or bowel washing, fever which declined rapidly in those that recovered, extremely rapid pulse, with rapid, shallow respirations, and terminal cyanosis and convulsions. The children that recovered all developed abscesses at the site of inoculation, from which later on *S aureus* was cultured in five cases.

The pathological evidence was similarly incomplete, since no trained pathologist was available for examining the bodies, except in one case, and that was only after an interval of fifty-two hours. Autopsies were performed in nine cases, but there was no bacteriological examina-

*A comprehensive report is to be found in *The Medical Journal of Australia*, Vol. II, Nos 1 and 2, July 7th and 14th, 1928.

tion of the blood or other tissues, microscopical sections were not made, and what material was kept for later examination was not suitably preserved, and yielded but little information. Again, however, it was possible by careful analysis of the information available, for the Commission to reach fairly definite conclusions. In their opinion the post-mortem findings indicated an acute toxæmia of an unspecified nature.

The next step was the examination of the unused contents of the bottle of antitoxin, and here the most important evidence was obtained, since it was found that the material was heavily infected with *S. aureus*, identical with the form isolated from the local abscesses. The serum was undoubtedly sterile at the outset, and that it was possible to keep it so by careful sterilization of the cap before each puncture, and by not allowing long intervals to elapse between each withdrawal, was shown in the case of other practitioners who followed these precautions with the same stock bottles, and who had no mishaps, moreover bacteriological examination of these other bottles proved them to have remained sterile. The fatal inoculations had been performed with admittedly imperfect technique, in a room not specially free from dust, and with an electric fan keeping up a current of air. It was shown experimentally by the Commission that contamination of the bottle under these conditions could have occurred very readily.

Among the many interesting points raised by these facts we may refer to the extraordinary, if not unprecedented, rapidity with which the

symptoms developed after the injection, even granting that living organisms were in the serum. So striking was this feature that it was necessary to consider the possibility of death having been due to anaphylactic shock. This view, however, was set aside as not being in full accord with the facts: the symptoms had appeared on the first injection in some cases, and the interval between the first and second doses was too short in others, nor did the post-mortem findings point to a state of anaphylaxis. It is difficult also to see why there should have been such complete and uneventful recovery in some of the cases, except for the development of mild local suppuration. Metastatic abscesses were more to be expected, but even the blood cultures taken on the third and fourth days of illness were sterile, as was also the blood in the case of the one autopsy which was fully carried out, although late after death. Finally, three of the children showed no effects at all from the same doses (apparently) of living organisms as proved fatal to twelve others. The theory of variation in susceptibility may be invoked to account for the differing reactions, but this explanation must of necessity be used guardedly.

These unusual responses, however, added considerable weight to the belief that living organisms and their toxins were responsible, rather than the toxin-antitoxin itself. In the previous accidents quoted there had been marked and constant inflammatory infiltration of the tissues around the site of the inoculation, a feature which was present in none of the Australian cases.

Men and Books

JOHN HUNTER*

By THOMAS MCPHERSON, B.A., M.D., F.R.C.S.

Victoria, B.C.

John Hunter came of a very old Scotch family whose history goes back to the thirteenth century. He was born at Long Calderwood, a small estate near Glasgow. The house bears a tablet to the effect that he was born on February 13th, 1728. He himself observed the 14th as his birthday, and that is the day of the Hunterian oration at the Royal College of Surgeons. Probably he was born so late at night that they failed to notice whether he appeared just before or shortly after the clock struck twelve.

John was the last of ten children. The first three died in childhood, four others in the prime of life. James, the first son to grow up, died of phthisis at the age of twenty-nine. He was handsome and clever, and William Hunter used to say that he was the brightest of the family.

* An address delivered before the Victoria Medical Society, April 20, 1928, on the occasion of the Bicentenary of the birth of John Hunter.

and if he had lived nothing could have prevented him from being the first physician in London. A sister, Dorothea, married the Rev. James Baillie, afterwards Professor of Divinity at Glasgow, and had three children, Matthew, who became a famous physician in London, Johanna, who was the "Immortal Johanna," one of Sir Walter Scott's closest friends, and Agnes, whose claim to distinction lay in the fact that she lived to the very great age of 100. John's brother William, too, was one of the masters of medicine, and it was he who set John on his way. William started to read for the ministry, but changed his mind. For three years he lived with Cullen at Hamilton, helping with the uphill work of a country practice. In the summer of 1741 he went to London, where he became assistant to Dr. John Douglas. In 1746 he began to lecture on the operations of surgery and on anatomy.

John, throughout his boyhood, was good at games and observant of nature, but idle and ignorant, a great disgrace for a Scotch boy whose father was a gentleman and whose brothers were studying law and medicine. He hated school books. When seventeen years old he spent a

few months in the timber-yard of his brother-in-law at Glasgow, but did not work and soon returned home. At twenty, he wrote to his brother William asking leave to come and work with him.

The two brothers began to work together in September, 1748. Their temperaments were very different. Reynolds has presented William as a fine gentleman, well dressed, carefully posed, his hands delicate, his features regular and remarkably handsome. In notable contrast is Robert Home's portrait of John Hunter in his working dress, a loose dissecting apron with long sleeves, the cuffs turned back, the garment caught about him with a single button. His attitude is clumsy and his features have none of his brother's good looks. They lack the fineness, but the whole face and figure are full of indomitable strength.

Fortune was favouring William. In 1748 he was appointed physician-accoucheur to the Middlesex Hospital, and the next year surgeon-accoucheur to the British Lying-in Hospital. John Hunter was studying anatomy, and for his lighter studies was seeing something of hospital practice. He was demonstrating to the students and doing the rough work, slaving all day, dissecting and putting up specimens. For two years he worked with Cheselden at Chelsea Hospital. In 1751 he became surgeon's pupil at St. Bartholomew's Hospital, under Percival Pott, whose simplicity of treatment and avoidance of officious interference had made him great in surgery. There was little hope of his becoming a member of the staff at St. Bartholomew's, so he later entered himself as surgeon's pupil at St. George's. He went for a time to Oxford, but left in less than two months. For five months he was sole house surgeon at St. George's.

About this time he began to study comparative anatomy, dissecting different animals, noting different forms and arrangements of organs, and observing them alike in health and in disease, in the hope that he might thereby acquire some knowledge of general principles.

His health was not good and in 1760 he was appointed staff-surgeon in the army. The appointment gave him change of work, a voyage, and an abundance of surgery, especially gunshot wounds. In 1761 he went with the fleet to Belle Isle, a small island off the coast of France, and the next year was staff surgeon in the expedition to Portugal.

William Hunter was hard at work in town. He held two hospital appointments, his private practice was one of the largest in London, and he was doing much literary work, but still found time to proclaim and protect his brother's discoveries in anatomy, among these being the lachrymal ducts and of the tubuli seminiferi in man, those relating to congenital hernia, concerning which there was much controversy with Percival Pott, the absorbent system, a new truth, second only to Harvey's discovery of the circulation of the blood. Over this there was a great deal of dispute with the Monros of Edinburgh

as to whom credit was due. Later, when the two brothers separated, a paper which John gave before the Royal Society on the structure of the placenta caused a lengthy dispute between them.

John Hunter returned from the Peninsula and started practice in Golden Square when he was thirty-five years of age. He was only one more surgeon amongst men of greater experience, including, particularly, Percival Pott. He had no hospital appointment and had been away for more than two years. Moreover, his passion for scientific work delayed his success as a surgeon and dominated the opinion which men had of him.

In 1764 he bought two acres of land at Earl's Court, and built himself a small house. Here he kept his animals and experimented on them. It is recorded that he used to wrestle in play every day with a beautiful small bull which he had received from the Queen. On one occasion it got him down and he was saved only by the accidental appearance of a servant who frightened the animal away. Again, two leopards broke from their confinement and got among some dogs, which they immediately attacked. The howling this produced alarmed the whole neighbourhood. Mr. Hunter ran into the yard to see what the matter was, and found one of them getting up the wall to make his escape and the other surrounded by the dogs. He immediately laid hold of them both and carried them back to their den, only later realizing his great danger. It was here, too, that he did many of his dissections and kept many of his specimens, for he was a most assiduous collector. A remarkable instance of this is recorded in connection with the Irish giant, O'Brien. Hunter was very anxious to get the skeleton of the giant and hearing that his health was bad had him followed. O'Brien, becoming alarmed at this, made arrangements that his body should be watched after death until a lead coffin could be prepared, in which he was to be buried at sea. After O'Brien's death Hunter got in touch in a public house with the men guarding the body and offered a bribe of £50 to be allowed to steal the body. He appeared eager and the watchers gradually increased their demands until they reached £500, which Hunter borrowed and paid them. He carried the body in his own hackney coach to Earl's Court where he himself prepared the skeleton.

In 1767 Hunter was elected a Fellow of the Royal Society, without having submitted to them any of his works. In the same year he ruptured his tendo Achillis by dancing. Following this he made experiments on dogs, dividing the tendons subcutaneously, and afterwards killing the dogs at different periods to observe the process of repair, thus foreshadowing Stromeyer's work in subcutaneous surgery. On September 9, 1768, he was elected surgeon to St. George's Hospital. This election was of infinite value to him, for a surgeon without a hospital is like a gardener without a garden.

The appointment also gave him the right to have house pupils. Soon after this he was made a member of the Corporation of Surgeons. When William Hunter moved from Jermyn Street to Great Windmill Street John took over the lease of his brother's house in Jermyn Street and moved into it from Golden Square, thus acquiring a good house in a fashionable part of London, near the hospital and already known as a doctor's house.

In July, 1771, John Hunter, at the age of forty-three, married Ann Home. The first child was named after his father. Another son and a daughter died in childhood, and there was another daughter, Agnes. The son John went to Cambridge, entered the army and became a colonel. Neither Agnes nor John had any children. Mrs Hunter was beautiful and clever and took her place high in society. She was the friend of clever people. She wrote "My Mother Bids Me Bind My Hair," and also the words for Haydn's "Creation." In 1772 Mrs Hunter's young brother, Everard Home, became the house pupil of Hunter, and much of our information about Hunter comes from his writings.

The following year Hunter had his first attack of serious illness. He describes this himself fully, and in the *Lancet* of February 18th, 1928, there is an article by Dr John A. Ryle suggesting that this illness was due to thrombosis of the coronary artery, with infarct of heart. He was free until 1776 from further attacks and after this had long intervals of freedom, but towards the last had pain every day.

In 1773 he gave his first course of lectures on the Principles of Surgery. The labour of preparing and delivering these magnificent lectures was very heavy. There was nothing like them in London, for their comprehension of the whole circle of the sciences round surgery. The fee for this course of nearly one hundred lectures was four guineas, making the cost to the hearer but ten pence per lecture. In 1776 he was appointed Surgeon-Extraordinary to the King, his brother having been for twelve years already a member of the household. William Hunter died on Sunday, March 30, 1783. In his will he did not so much as mention his brother John, showing the bitterness of their estrangement.

Many of John Hunter's pupils afterwards became famous. Amongst them were Sir Astley Cooper, Abernethy, Physic of Philadelphia, Cline, and Edward Jenner. Many letters from Hunter to Jenner have been published. These all show the intense interest which Hunter took in all kinds of life, cuckoos, hedgehogs, eels, salmon, bats, trees, porpoises, fossils and many other things. There is also a letter written a few months before he died to a friend in Africa, asking about swallows, ostrich eggs, camels, cuckoos, and the like.

In 1783 his lease in Jermyn Street came to an end. His collection had outgrown that building, so Hunter bought the lease of a large house in Leicester Square. He also bought ground be-

hind it, running to what is now Charing Cross Road, and at a cost of about £6000 erected his famous museum. There is a tradition that Stevenson drew from these premises his picture of the house and museum of Dr Jekyll. From now on his health was bad. He suffered almost daily attacks of pain. Latterly, these were brought on by the slightest exertion. He gave up the use of wine. Earlier, he had been a heavy drinker. About this time Sir Joshua Reynolds painted the portrait of him which is in the possession of the Royal College of Surgeons. Hunter was a bad sitter, but one day he fell into deep thought. Reynolds turned the canvas he was working on upside down and sketched a new head between the legs of the figure he had already painted. On the occasion of each Hunterian Oration this picture is hung opposite the audience and above the orator.

In 1788 Percival Pott died, and Hunter was now undoubtedly the head of his profession. His consultations were more in fashion than any other surgeon's and his range of practice more extensive. The next year Hunter succeeded Mr Adair as Surgeon-General and Inspector-General. His health became worse and worse. He was growing old, more from illness than from years. He had given up his lecturing, which was carried on by his brother-in-law, Mr Home. For the first fifteen years following his appointment Hunter worked fairly well with his colleagues at St George's, but from that time on he began to have disputes with its surgeons, on the ground that they were not doing enough for the pupils of the hospital. In this year, 1783, the proposal was made by Hunter, or at least supported by him, that a medical school should be created, after the model of the Guy's Hospital School, and that each surgeon should give six lectures on surgery. It was not approved by Hunter's colleagues, for reasons which for the most part seem to have been dictated by a feeling of opposition to Hunter, and not by any valid grounds of argument.

In 1793, the year of his death, Hunter declared that the entrance fees of pupils should no longer be divided equally among the surgeons, and that he would keep for himself the fees of those who entered under him. Whether he wanted the money, or whether he thought by this plan to force his colleagues to do more teaching we do not know. The three other surgeons appealed to the Governors, and there was much argument for and against. The Court of Governors decided against Hunter. That autumn two young men came to be admitted to the hospital under him without certificates that they had been "bred up to the profession" and Hunter promised that he would nevertheless ask the Board to let them enter, bringing up their case at the next meeting on Wednesday, October 16th. On the Wednesday morning he saw one of his friends and told him what was to happen at the meeting. He said he was sure there would be a dispute and it would be the death of him. He went into the

workrooms and told his resident pupils some droll stories and left the house in good spirits, whistling a Scotch air. The meeting had already begun when he reached the hospital. He presented the memorial from the young men and spoke on their behalf. One of his colleagues flatly contradicted something he had said. Then came the end. Angina seized him, he turned toward another room to fight out his pain by himself, and Dr. Matthew Bailhe followed him. He went a few steps, groaned, and fell into Dr. Robertson's arms and died.

Hunter's work had been multitudinous. He was anatomist, biologist, naturalist, physician, surgeon, and pathologist, all at once and all in the highest degree.

In person he was five feet, two inches high, strongly built, and toward the end of his life somewhat corpulent, his shoulders were broad and high, his neck very short, he was uncommonly strong and active, compactly made, and capable of great bodily exertion. His hair was of a reddish tint, afterward grey, at last white, his eyes were light. He dressed plainly and not always neatly.

In consultation he was deliberate and of many words. With his patients he made no mystery of their cases and enjoyed illustrating them from the natural history of lower forms of life. He was fond of quoting the names of distinguished patients. There are many stories of his generosity. He was especially kind to poor artists and to poor doctors. He loved his home life and liked his friends to call him by his Christian name.

He had a habit of saying, "I cannot tell at present what to recommend. I must think of it." To Astley Cooper, who asked with surprise whether he had not the year before stated an opinion on some point directly at variance with one he had just put forth, he replied, "Very likely I did, I hope I grow wiser every year," and to the same purport he answered another of his pupils who asked whether he had not written so-and-so, "Never ask me what I have said, or what I have written, but if you will ask me what my present opinions are, I will tell you." Again, "You had better not write down that observation, for very likely I shall think differently next year." And, finally, let me remind you that it was Hunter who said, and the saying dominated his whole life, "Don't think. Try."

The Dosage of Drugs—In his preface to the new (nineteenth) edition of *The Extra Pharmacopoeia* Dr. W. Harrison Martindale raises an interesting point about the dosage of new drugs. He remarks that in the case of many of the important and powerful drugs that have been introduced in recent years the dose originally recommended has been found by experience to be dangerously high, and he pleads for more care in the application of results derived from animal experiments to the calculation of doses suitable for therapeutic use. This is a very timely warning, and everyone will agree with the opinion of a scientist whom he

LINACRE'S INFLUENCE ON ENGLISH MEDICINE

"Thomas Linacre (1460-1524), the prototype and father of the scholar physicians in this country, exerted a lasting influence on medicine by founding the Royal College of Physicians of London in 1518, and brought the spirit of Greek learning into the intellectual life of the country. By his will he also established lectureships at the two older universities, but unfortunately these did not fulfil the intentions of the pious founder, for example, at St. John's College, Cambridge, the lectureship became a college appointment and largely a sinecure, twenty years ago, however, the character of the office there was changed, and a distinguished leader in medicine was appointed each year. In 1908, as the first lecturer under the new regulations the late Sir William Osler gave an account of Thomas Linacre's life, of his activities as a medical humanist and a grammarian, and of the history of the Cambridge foundation, in 1913 the late Sir Norman Moore discoursed in his inimitable manner on "The Physician in English History," and on May 5th last Sir George Newman read an essay, both learned and delightful, on Linacre's influence on English medicine, which has just been attractively printed for private circulation as a pamphlet of 37 pages. Though the subject is much the same as Sir William Osler's it is treated on different lines, and the reader realizes that these two scholarly essays are complementary to each other. Going to Italy with a scholastic grounding in the classics, Linacre brought back to England a living comprehension of the service which pure Hellenism could render to English medicine, of the essential importance of Aristotle, and of the necessity of a re-orientation of medical knowledge as transmitted by the Arabs. In conclusion, Sir George Newman points out that, although Linacre and his pupil Sir Thomas More knew that the future well-being of the English nation lay with simple methods of prevention, this practice is still widely disregarded. Readers of the author's book of essays, *The Interpreters of Nature* published last year, will naturally hope that in its second edition the Linacre Lecture of 1928 will be included"—*Brit. Med. Jour.*, 1928, ii, 25

quotes as saying, that in the case of a new drug "the clinical trial, properly conducted, ought to involve a research as careful and elaborate as the preliminary laboratory demonstration of a promising activity"—*Brit. M. J.*, 1928, ii, 262

An Anticipation of Listerism—"It is not necessary, as modern surgeons teach, that pus should be generated in wounds. No error can be greater than this. Such a practice hinders Nature and prevents the agglutination of the wound"—*Theodorico of Bologna, Bishop of Cervia*, (1205-1295)

Provincial Association Notes

PROVINCE OF QUEBEC MEDICAL ASSOCIATION

The annual clinical day of the Province of Quebec Medical Association will be held in Sherbrooke, on Tuesday the 18th of September next

The forenoon will be devoted to clinical and scientific work, the afternoon to social functions

A special committee has been appointed to entertain visiting ladies who may accompany members

During the evening there will be a banquet, followed by the annual general meeting of the Association, during which will be discussed subjects of interest to the profession in general

The registration fee of \$2.00 includes membership in the above Association

PRELIMINARY PROGRAM

- 8 00 a.m. Clinics in the different hospitals of the city St Vincent de Paul General Hospital, King Street (east), Sherbrooke General Hospital, Park Avenue (Tramways of the Park Lane), Hôtel Dieu, Bowen Street (south) (Tramways of the Newington Line)
 - 10 30 a.m. Inscription at the St Vincent de Paul Hospital, payment of the annual fee to the Province of Quebec Medical Association, and mission cards to the night banquet.
 - 11 00 a.m. Lectures in the large Reception Hall of the St. Vincent de Paul Hospital (3rd floor, Administration Building)
Lecturers Doctor C Jeannin, Professor at the Medical Faculty of Paris, France, will speak on "Eclampsia."
Doctor F. H. Lahey, Chief of the Lahey Clinic, of Boston, Mass., U.S.A., will speak on "Abdominal surgery and the general practitioner"
 - 1 00 p.m. Luncheon at the St Vincent de Paul Hospital
 - 2 00 p.m. Automobile trips to the Little Lake Magog (9 miles from Sherbrooke), and North Hatley (15 miles from Sherbrooke)
Fishing, bathing, golfing, etc., etc.
For the Ladies Bridge and tea at the "Country Club," organized by Mrs (Dr) Gordon Hume, Dr J. A. Darche, Dr F. Bertrand, Dr J. A. C. Ethier, Dr H. C. Cabana.
 - 6 00 p.m. Automobile tour of the city
 - 7 00 p.m. Banquet at the Magog House, Dufferin Avenue.
Orators Doctor C. F. Martin, Dean of the Medical Faculty of McGill University, Montreal
Doctor L. de L. Harwood, Dean of the Medical Faculty of Montreal University, Montreal
President Doctor Gordon Hume
 - 9 00 p.m. General meeting in the Magog House Lobby or at the City Hall
- To be discussed Bill of the Canadian College of Surgeons and Physicians, Health certificate before marriage, Workmen's Compensation Act of the Province of Quebec, etc., etc.
All members of the Province of Quebec Medical Association can join in the discussion
- 10 30 p.m. Annual reports of the Secretary and

Treasurer, with remarks by the General President, Doctor Stevenson of Quebec City
Elections

11 00 p.m. Smoking (Grill Room of the Magog House)

PRINCE EDWARD ISLAND MEDICAL ASSOCIATION

The annual meeting of the Prince Edward Island Medical Association was held in Charlottetown on July 11th. The morning session began at 10 30, with the President, Dr J. C. Houston, in the chair

After the routine business was disposed of, the following communications from the Canadian Medical Association were considered

1 *Re* Lister Day

The Prince Edward Island Medical Association will celebrate this event each year in a fitting manner

2 *Re* Membership Fees

The Association is favourable to the suggestion that the fees be collected in October instead of January

3 *Re* Venereal Disease as an impediment to marriage

After considerable discussion it was decided to refer this matter to the Medical Council of the Province.

Touching reference was made to the death of Dr James Warburton, who was one of the oldest and most respected physicians of the Province

Dr S. R. Jenkins, President of the Canadian Medical Association, congratulated the different committees on their splendid work, and their almost perfect organization, which had as a result the staging of one of the most successful meetings of the Dominion Association

Regarding the fifty-ninth meeting the writer of these notes has had many letters of appreciation from our guests on that occasion, particularly stressing the wonderful hospitality of our Island people. While all these expressions were satisfying and welcome, one fact stands out prominently, and seems the most important of all, namely, that the work of the committees received the praise of the officers of the Association, who not only expect but demand efficiency when the success of this important meeting is at stake

The following officers were elected for the ensuing year —

President, Dr E. E. Sinclair

Vice Presidents, Drs Preston McIntyre, J. B. Champion, and James Walsh

Treasurer, Dr I J Yeo
Secretary, Dr G F Dewar
Auditors Drs W McKenzie and G L Smith
Executive Committee, Drs W J McMillan, I F McNeill, and B C Keeping
On the Canadian Medical Association Council, Drs I J Yeo, H D Johnson, and W J McMillan
Editorial Board, Canadian Medical Association Journal, Drs W McKenzie and J A McPhee
Medical Council of Prince Edward Island, Dr S R Jenkins (Registrar), Dr I J Yeo (President), Dr G F Dewar (Treasurer), Drs H D Johnson, W J McMillan, E T Tanton, and J F McNeill

PRESIDENT'S ADDRESS

The President, Dr J C Houston, in delivering the annual address, took as his subject "Examination of the urine and its aid in diagnosis."

He said the examination of urine was not a very pleasing occupation, and the general practitioner is often tempted to be satisfied with a few easy tests done in a rather careless manner taking as little time as possible. Very often, if there are no symptoms of disturbed kidney function, he neglects or forgets to ask for even a single specimen, and a twenty-four hour specimen would be far too much trouble.

He emphasized the importance of a routine examination, for in this way many obscure cases can be correctly diagnosed. He instanced a case which had been treated for pulmonary tuberculosis and which, under suitable hospital treatment and careful examination of the urine, turned out to be a case of pus-kidney. Another case was admitted to the hospital with a history of Bright's disease, which on careful examination of the urine, and x-ray, turned out to be a case of calculus in the ureter with a large dilated kidney.

Dr Houston outlined the method of routine examination of the urine as practised in the Prince Edward Island Hospital, and showed that it must be so exact that any disease which has its origin in the kidney can be eliminated.

One cannot do justice to this excellent paper in a brief synopsis. It was felt by all present the President had chosen a very timely subject for his annual address, one which was of real practical value to the practitioners of the province.

The speakers at the afternoon session were Dr Grant Campbell, of the Alexandria Hospital Montreal, and Lecturer in Medicine at McGill

University, and Dr J R Goodall, of the Royal Victoria Maternity Hospital, Montreal, and Clinical Professor of Gynaecology and Obstetrics at McGill University.

Dr Campbell first considered measles, which next to small-pox is the most infectious of the contagious diseases. He went carefully into every phase of the disease from the incubation period to convalescence, also noting the most serious complications.

He then addressed the meeting on the modern treatment of scarlet fever. He went very minutely into special treatment such as antitoxin, and also spoke of the complications of this important disease. His papers, for which he received the thanks of the Association, were of a very high order.

Dr Goodall's first address was on pelvic infections, which he divided into two groups (1) Those independent of pregnancy (2) Those connected with pregnancy. He went carefully into the causation, course and the most suitable treatment to adopt.

Dr Goodall next dealt with eclampsia. He explained the preventive treatment for this dread disease, the symptoms, course, and the treatment of the attack were described in detail.

The Association thanked Dr Goodall for his very instructive papers.

The Prince Edward Island Medical Association appreciates the kindness of the Canadian Medical Association in sending such excellent lecturers to address its meetings.

G F DEWAR

BRITISH COLUMBIA MEDICAL ASSOCIATION

At the first meeting of the new Executive of the British Columbia Medical Association, held after the annual meeting in Victoria, chairman of standing committees were elected as follows: Dr M W Thomas, Victoria, Legislative Committee, Dr J H MacDermot, Vancouver, Industrial Service Committee, Dr W T Ewing, Vancouver, Constitution and Credentials Committee, Dr D G Peery, Vancouver, Publicity and Educational Committee, Dr J W Aibuckle, Vancouver, Ethics and Discipline Committee.

"In writing, therefore, such a natural history of diseases, every merely philosophical hypothesis should be set aside and the manifest and natural phenomena, however minute, should be noted with the utmost exactness. The usefulness of this procedure cannot be easily overrated, as compared with the subtle enquiries and trifling notions of modern writers, for can there be a shorter, or indeed any other way of coming at the morbid causes,

or discovering the causative indications, than by a certain perception of the peculiar? By these steps and helps it was that the father of physics, the great Hippocrates, came to excel, his theory being no more than an exact description or view of nature. He found that nature alone often terminates disease, and work a cure with a few simple medicines, and often enough with no medicines at all."—Sydenham (1624-1689)

Medico-Legal

MEDICAL COMMUNICATIONS

We are indebted to the *Manitoba Medical Bulletin*, June, 1928, for the following notes on a Supreme Court decision re medical communications.

"In giving judgment in an appeal before the Supreme Court of Canada in February last the Court had to deal with the communication by a physician of information supposed to have been obtained by him under the seal of professional confidence from a patient. The facts were briefly as follows:

Dr M in 1924, as assistant chief medical officer of a railway company, was investigating a claim for workmen's compensation by H, due to an attack of iritis which permanently affected H's vision. In 1920 H had been a patient of Dr M. In the course of his inquiries as such medical officer, Dr M wrote, among other things, to another physician referring to H: 'He also stated that he had had g.c. infection about 1918.' H brought action for damages for libel against Dr M. At the trial the judge held that in fact H had not informed Dr M that he had suffered from the malady mentioned. The trial judge's decision was reversed by the Appellate Division and H's action was dismissed. On appeal by H to the Supreme Court of Canada that Court decided in favour of H, and found that there was no adequate ground for disagreeing with the finding of the trial judge, that H's account of his interviews with Dr M should be accepted and that the entry in Dr M's notes on the subject of g.c. infection was the result of an error."

The following are quotations from the majority judgment of Mr Justice Duff in the Supreme Court:

"We are not required, for the purposes of this appeal, to attempt to state with any sort of precision the limits of the obligation of secrecy which rests upon the medical practitioner in relation to professional secrets acquired by him in the course of his practise. Nobody would dispute that a secret so acquired is the secret of the patient, and, normally, is under his control, and not under that of the doctor. *Prima facie*, the patient has the right to require that the secret shall not be divulged, and that right is absolute, unless there is some paramount reason which overrides it. Such reasons may

arise, no doubt, from the existence of facts which bring into play overpowering considerations connected with public justice, and there may be cases in which reasons connected with the safety of individuals or of the public, physical or moral, would be sufficiently cogent to supersede or qualify the obligations *prima facie* imposed by the confidential relation.

The general duty of medical men to observe secrecy, in relation to information acquired by them confidentially from their patients is subject, no doubt, to some exceptions, which have no operation in the case of solicitors, but the grounds of the legal, social or moral imperatives affecting physicians and surgeons, touching the inviolability of professional confidences, are not, any more than those affecting legal advisers, based exclusively upon the relations between the parties as individuals.

It is, perhaps, not easy to exaggerate the value attached by the community as a whole to the existence of a competently trained and honourable medical profession, and it is just as important that patients, in consulting a physician, shall feel that they may impart the facts touching their bodily health, without fear that their confidence may be abused to their disadvantage.

Considering the present case from all these points of view, I am unable to agree that the duty of a chief medical officer of an industrial concern, for example charged with investigating a claim made by an employee for compensation under the Workmen's Compensation Act, and in preparing the evidence, is so 'situated' that 'it,' to use the language of Blackburn, J, in *Davies v Snead* (1), 'becomes right in the interests of society that he should tell,' for the purpose of securing information in preparing his case, the facts he has confidentially ascertained from the claimant as his personal medical adviser, or that he is under a duty recognized by people of 'ordinary intelligence and moral principle,' to divulge such facts without the assent of the patient.

There was no duty resting upon the respondent, and no interest committed to his charge, of sufficient weight and importance to require that the libels in question, involving the disclosure of professional confidences should be protected in the 'general interests of society.'"

Correspondence

The Edinburgh Letter

(From our own correspondent)

There has been an alarming increase in sickness and disablement claims in Scotland under the National Health Insurance Act. This is a matter of serious importance to the various Friendly and Approved Societies who have to meet these claims. Each year has been worse than the preceding year. It was thought by many that the large expenditure in 1926 under this heading was due to the effect of the coal strike, and that it was merely a temporary phase, but that explanation is no longer adequate to account for the still rising tide of claims. In 1925, the amount spent upon sickness and disablement benefit was £1,570,000, in 1926 it was £2,020,000. Taking disablement benefit alone, the expenditure in Scotland has practically doubled in the last four years. Sir James Leishman of the Scottish Board of Health, in addressing a conference of members of the Approved Societies in Edinburgh recently, drew attention to these figures. He pointed out the interesting fact that while the bill for disablement benefit is increasing, the figures do not represent a growing decline in the health of the working population. As a matter of fact the health of the community has been good, the death rate of 13.5 per thousand being almost at its lowest. Sir James Leishman suggested that a more probable explanation is that the increase in the sick benefit is to a certain extent due to lax certification by doctors. Most of them no doubt are doing their duty by the Act fairly, but even a small minority of the doctors, particularly in the industrial areas by granting certificates on inadequate grounds can cause a considerable increase in the figures. Sir James mentioned that in Northern Ireland, where experience has also been bad, nine doctors had been put off the panel within the past four months, and he added that it might be that in proved cases of persistent lax certification a like procedure would have to be adopted in Scotland. But the Societies can also help by a more effective supervision of cases, and by greater use of the medical referees. Nobody desires that good claims should be rejected, but, as Sir James Leishman said, the Societies should be careful of doubtful ones, while as trustees they are bound to refuse all bad claims.

"An inquiry into Post-Operative Tetanus, a Report to the Scottish Board of Health by T. J. Mackie, M.D., Professor of Bacteriology in the University of Edinburgh" has just been issued. Dr. Mackie in his conclusions and

recommendations says "At the present time there is no control by any health authority over the manufacture of surgical catgut liable to carry dangerous bacterial spores and intended for introduction, sometimes in large quantity, into the tissues. The same control as that now exercised, under the Therapeutic Substances Act, by the Ministry of Health (in England) and the Scottish Board of Health over the manufacture of vaccines, antisera, and certain other biological products, should be applied to catgut, such control would assist and guide manufacturers of surgical catgut in standardizing their methods and safeguarding their products. Under the Act referred to, rigorous sterility tests are demanded in the case of antisera, vaccines, etc., there is the same need for bacteriological control tests of catgut supplied in sealed tubes and "guaranteed" to be sterile. When catgut is supplied in the form of dry strands these should be free from sporing anaerobic bacilli of direct intestinal origin—*e.g.*, *B. Welchii*. At the same time, surgeons and others who undertake the responsibility of preparing these strands for operative use should ensure that their methods of sterilization and technique of manipulation, storage, and distribution are such as to yield a perfectly sterile product."

The 33rd annual meeting of the Church of Scotland Deaconess Hospital (Lady Grisell Baillie Memorial) was held recently. This hospital is situated in the Pleasance, formerly a charming residential area, but now a less salubrious locality. The institution contains 50 beds, and provides treatment for medical, surgical and gynaecological cases. During the past year there has been an increase of 99 in the number of cases treated, and the total of 782 is the largest in the history of the institution. In regard to out-patients the hospital has been over-run. People come from all parts of the city and the neighbouring counties to obtain advice and treatment. The Deaconess Hospital is unique in Scotland, if not in Great Britain, as it is the only hospital administered by a church. It was instituted for the twofold purpose of ministering to the sick and the suffering, and also as a place of training for those women who are going to devote their lives to missionary work in this country and beyond the seas. Both these aims have been amply maintained in the past, and we can still claim that the Deaconess Hospital has a very real and honourable position among the charities in Edinburgh. The hospital has always been fortunate in obtaining the services of some of the most celebrated physi-

cians and surgeons in Edinburgh. The late Dr G. A. Gibson, Professors Alexis Thomson and F. D. Boyd, were formerly members of the hospital staff, as was W. T. Ritchie the present professor of medicine in the university.

An extension to the Stornoway Hospital, Lewis, has just been opened. Lewis is the largest and most important of the Outer Hebrides, and together with Harris the population numbers 32,000 people who are scattered over a wide area. Until the advent of the motor car medical practice was undertaken under conditions of great difficulty. To this day the superstitions of a former day still linger in the ministrations of hereditary healers and bone setters. Until recently the local people looked upon a hospital merely as a place in which to die, and avoided it as sedulously as a prison, an asylum or a morgue. There has been a hospital in Stornoway since 1896. This old hospital was enlarged in 1920 to contain about 20 beds. Owing however to the superstitious dread of the people it was never fully occupied. In 1924 with the financial assistance of the Scottish Board of Health under the Highlands and Islands Medical Service Act, a consulting surgeon was appointed. Recently a further grant has made it possible to enlarge the institution along the most modern lines of diagnosis and treatment. A modern x-ray plant, with a complete apparatus for screening and photographing, has been introduced, as well as a light treatment department, where mercury-vapour lamps for artificial sunlight treatment will be installed. Under the present arrangement the Medical Officer of Health for the island, who lives in Stornoway, acts as an anaesthetist. In 1923 which was the last year in which the old arrangements were in force, less than 100 cases were admitted to the hospital. In 1926 with the enlarged surgical service 375 patients were treated and 350 operations performed. There were also more than one thousand out-patient attendances. Surgery in Lewis may still be said to be in its infancy and conditions are reminiscent of a mainland hospital twenty-five years ago. The people have not yet realized how much can be done by early treatment. Cases of cancer for instance are frequently admitted when all chance of a successful operation is past. The removal of enlarged tonsils and adenoids in children, until recently, was seldom carried out. It is only to-day that complicated midwifery cases are beginning to find their way into hospital. With this new and improved surgical service, the dread of the hospital is becoming completely removed, and the whole medical outlook of the people in the island is being changed.

Mr A. A. Scot Skirving, C.M.G., has retired from the Staff of the Edinburgh Royal In-

firmary. Mr T. M. Millar, F.R.C.S., has been appointed in his place.

GEORGE GIBSON

23, Cluny Terrace, Edinburgh

The London Letter

(From our own correspondent)

The ninety-sixth annual meeting of the British Medical Association was held in Cardiff during last month and a very large and representative gathering took place. The Association had visited Cardiff forty-three years before, and the President, Sir Ewen Maclean, Professor of Obstetrics and Gynaecology in the Welsh National School of Medicine, in his address recalled some of the work of the Association at and since that meeting in 1885. It is difficult to summarize in a brief paragraph any of the valuable discussions concerned with the organization of the Association or with the various subjects brought up in the scientific sections but two things do stand out by reason of their novelty. In the first place there was a proposal brought forward that the British Medical Association should become a full member of the "Association Professionnelle Internationale des Médecins" (A.P.I.M.). The Council had decided against this, but the meeting expressed itself by a majority in favour of supporting such a body and instructed the Council to take the necessary steps. The other subject which roused a great amount of interest concerned the proposed paying centres for infant hygiene. Mothers of the middle and upper classes, it appears, are beginning to look with longing eyes on the care and counsel obtained by their poorer sisters at infant welfare centres and desire a similar sort of clinic for themselves. Those who took part in the discussion seemed very frightened at what appeared to be yet another encroachment upon private practice and the meeting approved of urging mothers of these classes to stick to the family doctor. There are experts who prophecy that a state medical service is not very far distant. The general practitioner, as represented at Cardiff, is going to prove a bit of a difficulty it seems, and it is interesting to speculate whether, in terms of industry, he ought to be nationalized or rationalized.

One of the most important international conferences on cancer ever held has just concluded its meetings in London, when delegates from abroad to the number of over one hundred met more than two hundred of their British colleagues. One is constantly being told in the daily press that the solution of the cancer problem is to be obtained by putting a vast number of experts in a position to work uninterruptedly at various parts of the field and then after a period of time pooling their results.

Such a conference as has just been held does in reality represent just such a program as the newspaper writer brings forward as a novel idea. It is not belittling the immense amount of work which the organizers have done, nor the importance of the majority of the discussions held, to say that the problem of the causation of cancer is not much nearer solution as a result. This is not intended as a cynicism, the point is that facts are accumulated almost day by day and what is badly wanted is a fresh interpretation of them. At the conference Dr J W Murphy, of New York, described the results of his recent work which seemed to show that in cancer the "agent" was some endogenous chemical substance rather than an extrinsic living virus. Other speakers also negatived the claims of Gye and Barnard with regard to a cancer virus and yet this was hailed with great shouts only a short time ago. More hopeful were the discussions on treatment and there does now appear to be a well established technique for the use of surgery combined with radium which holds out increasing chances of success. For all that no spectacular advance was announced, the conference was undoubtedly of great value in promoting the interchange of ideas between experts of different countries.

In May, at a "social evening" held at the Royal Society of Medicine, Mr P B Tustin gave an interesting lecture on the production of clean milk and recently the Eighth World Dairy Congress was held in London, so that milk has certainly been very much before our

eyes. The Congress was attended by more than two thousand delegates representing forty-two countries, and considerable interest was shown in the various papers and discussions. The control of the milk supply is a problem which faces many countries, the cost of control, it was generally agreed, should be borne by the state, since, as Sir George Newman put it, the dairying industry is not a trade but a service for health. It is very misleading at the present time to have "Grade A" milk and "Certified" milk both on the market for the public is attracted by the former as being better than the latter. It was strongly urged that all milk, except that from tubercle-free cows should be pasteurized but the clean milk versus pasteurization controversy still goes on with unabated vigour. The delegates from this country were interested in various figures about the consumption of milk in the form of ice-cream. It appeared that in America in 1926 about three gallons of milk per head of population were consumed under this heading. It is agreed that the milk consumption in the British Isles is much too small, as was emphasized by Mr Walter Guinness, the Minister for Agriculture at the opening session, and perhaps it might be increased by such a side line as ice-cream. Meanwhile a certain chocolate firm is trying to help with its slogan "Eat More Milk."

Faculty of the Severance Union Medical College, Seoul, Korea
1 Dr D B Avison 2 Dr N Found 3 Dr O R Avison (President) 4 Dr S H. Martin

To the Editor *

I take pleasure in inclosing an article which may be of interest, from which you can take extracts for the *Journal* as it shows some of the work that is being done by Canadian physicians in Korea.

The inclosed photograph of the Faculty has in its group Dr. D. B. Avison of Toronto, son of the President, who is Superintendent of the

* An abstract of the article to which Dr. Martin refers will be found under "General News." The *Journal* is pleased to be remembered so pleasantly by its friends and to form a link of union between the members of the profession in far off lands and their Canadian acquaintances. (Ed.)

Hospital, and also Professor of Pædiatrics, Dr. Norman Fould, also of Toronto University, head of the Department of Pathology, and Dr. S. H. Martin, Professor of Medicine, a graduate of Queen's University. If you could manage to put in the inclosed photograph, we would greatly appreciate it because of our many friends in the Canadian medical profession.

With all good wishes for the fine work which you are doing,

Sincerely yours,

S. H. MARTIN, M.D.

PROTECTION FROM X-RAYS AND RADIUM EMANATIONS

At the second International Congress of Radiology held in Stockholm in July a series of recommendations by the British X-Ray and Radium Protection Committee, for the protection of workers in Radiology, were unanimously adopted by the delegates of the countries represented. These recommendations are of the greatest importance to every institution in our country that operates an x-ray machine, and should act as a guide in the planning of future installations as well as a check on present faulty installations. This synopsis will include only the most important items, the more technical portions being left for a study by the directors of each department.

Because it is well known that prolonged exposure to x-ray or radium causes definite and permanent injuries to the superficial tissues and derangement of the internal organs and changes in the blood, it is recommended, first, that the working hours of a full-time employee in x-ray departments be limited to seven hours a day for five days a week, the off-days to be spent as much as possible out of doors; second, such workers should have at least one month's holiday a year; thirdly, all x-ray departments should be situated on or above the ground floor level. All rooms, including dark rooms, should have large windows to admit sunshine and sufficient air whenever possible. All rooms should be provided with exhaust ventilations sufficient to change the air ten times an hour. All x-ray rooms should be decorated in light colours. X-ray rooms should have a minimum floor space of two hundred and fifty square feet. Dark rooms should have a minimum of one hundred square feet. Ceilings should be not less than eleven feet high.

The x-ray operator should place himself in a position as remote as practical from the x-ray

tube and in the shadow of the target. The x-ray tube should be surrounded as completely as possible with protective material of adequate lead equivalent. In the case of x-ray therapy, the operator should not be in the same room, and should also have a protection of two millimetres lead equivalent. Fluoroscopic screens should have the protection of 15 millimetres lead equivalent. Screen examinations should be conducted as rapidly as possible with minimum intensities and small apertures. Fluoroscopic screens should be flanked if necessary by lead impregnated diaphanies. As a protection against scattered radiation protective gloves should be worn and should be lined with fabric or chamois leather.

The floor of the x-ray room should be a non-conductor of electricity, such as wood, rubber or linoleum. Overhead systems should be coronaless and at least nine feet high. All metal apparatus should be sufficiently earthed.

A. STANLEY KIRKLAND

DISEASES OF THE CORONARY ARTERIES*

"Sir Thomas Lewis, President of the Medical Section, who took the chair at the opening session of this section, said that the generalization associating a man's age with his arteries should be limited more particularly to the cerebral and coronary vessels. The discussion about to be opened was timely in view of the recent growth in knowledge about this subject, and it might be recalled that rather over a century ago a small group of men in the counties bordering Wales had contributed materially to the little that was then known.

* Abstract of a discussion that took place at the Cardiff meeting of the British Medical Association, July, 1928.

Dr G A Allan, in opening the discussion, said that disease of the coronary arteries had been recognized for a considerable time, and its association with angina pectoris had been widely accepted. In recent years prominence had been given to certain anginoid symptoms which had been found associated with coronary blockage, usually thrombosis. In this country the papers by McNee and by Gibson had helped to focus attention on the subject, but Lindsay Steven had made a careful analysis of the literature as far back as 1887. Coincident with this increased attention to the clinical aspect important anatomical investigations had been made by Gross and his collaborators, in addition to making an accurate survey of the part of the heart supplied by each coronary artery he had also shown that the heart was perhaps the richest organ in the body as regards capillary and pre-capillary anastomoses between branches of the same artery as well as between branches of both arteries, and that as age advanced there were anastomoses between the vessels in the epicardial fat and adjacent parts and the coronary arteries. The morbid processes affecting the coronary arteries might be classified into four clearly defined conditions: (1) Atheroma, the commonest primary lesion, was a patchy disease first affecting the deeper layers of the intima with degeneration of the deeper parts, proliferation of the fibrous elements, and encroachment on the lumen of the vessel. It was quite irregular in its distribution through the body, and might be well marked in the coronary vessels when there was no indication of it in the accessible arteries. (2) Arteriosclerosis, a diffuse process characterized by thickening of media and intima, probably beginning as a hyperplasia in the media, it was much more uniform in its distribution than atheroma. (3) Syphilis was comparatively rare in the coronary vessels in spite of the fact that aortic syphilis was one of the commonest visceral manifestations of the disease. (4) Calcification was most frequently found superimposed on either atheroma or arteriosclerosis, but it might occur as a primary medial degeneration, and its association with atheroma was a potent factor in diminishing the lumen of the vessel. To obtain some idea of the relative frequency of these lesions he had examined the figures collected from 1,000 consecutive autopsies in the Western Infirmary, Glasgow. In these there were 371 cases in which naked-eye lesions had been noted, the lesions were —

Atheroma	80.6% with fibrosis in 51.2%
Arteriosclerosis	45.3% with fibrosis in 54.7%
Calcification	10.8% with fibrosis in 77.5%
Syphilis	3.5% with fibrosis in 38.0%

Of 97 cases in which the coronary lesion was noted as producing definite narrowing of the lumen —

Atheroma	was present in 85, with fibrosis in 82%
Arteriosclerosis	was present in 31, with fibrosis in 84%
Calcification	was present in 33, with fibrosis in 85%
Syphilis	was present in 7, with fibrosis in 57%

Fifty-eight of the patients died suddenly, and in ten of these there was no evidence of fibrosis. Other points which emerged from this study were: (1) severe narrowing of the artery might be present without obvious myocardial lesion, (2) severe old-standing lesion and even occlusion might be present with no clinical history of its occurrence, (3) patients might die with symptoms suggesting coronary occlusion in which no such lesion was found. Disease of the coronary arteries in general tended to produce diminution of the lumen, thus caused starvation of the parts supplied, followed by replacement fibrosis, or, if sudden complete occlusion occurred, infarction resulted with subsequent fibrosis. It was apparent that there could be no diagnostic symptomatology to cover all cases of coronary artery disease, in the series quoted 35 per cent of cases showed no gross lesion of the muscle, and of the remaining 238 only 58 patients could be said to have died as the immediate result of the coronary lesions. When the blockage was abrupt certain features were present with such regularity as to make diagnosis reasonably sure, these would be dealt with by subsequent speakers. The features that demanded attention were the duration and situation of the pain, the associated symptoms such as vomiting, collapse, respiratory and mental distress, and such signs as the rate and rhythm of the heart, fall of blood pressure, etc., and the information to be derived from the electrocardiogram. The ultimate prognosis was in almost all cases bad, but judging from old lesions found at necropsy, those who made a good recovery, at least temporarily, must be fairly numerous.

Dr Carey F Coombs (Bristol), discussing the etiology of the two great coronary syndromes, ischaemia and infarction, gave an analysis of 1,600 cases of organic heart disease seen during the previous ten years. Both kinds of coronary attack occurred most often in the seventh decade of life, though ischaemia cordis was almost as frequent in the sixth, and appreciable in the fifth, partly owing to its relation to syphilis. Infarction was relatively more common in males than was ischaemia. Dr Coombs showed a slide indicating that cardiac rheumatism, ulcerative endocarditis, and cardiac syphilis seldom excited the coronary syndromes, except that ischaemia was more frequent in cardiac syphilis in consequence of the liability of the coronary orifices to stenosis in aortic syphilis. Some coronary disorders might, however, be traced to endocarditis lenta, and even a preceding phlebitis.

Dr Ivor Davies (Cardiff) commented on the importance of symptoms in disease of the coronary arteries, and referred especially to

intermittent peripheral arterial claudication. Coronary sclerosis might be considered as a generic term to include atheroma pectoris and coronary thrombosis. (*Brit M J* 1928 ii 198)

EARLY DIAGNOSIS IN MEASLES

Nearly eight years ago Prownke¹ observing that measles mortality is largely confined to the early age groups, advocated a concentration of effort toward the protection of young children. The idea was revived by Godfrey² in this country in 1926. In May of last year W. S. C. Copeman³ presented to the Royal Society of Medicine a method of securing this protection by the careful utilization of convalescent serum in patients under 3 years of age. Apparently quite unaware that even as he read his paper a successful demonstration of something like his scheme was in actual progress in the city of Syracuse, N. Y. Both plans stressed the importance of educational publicity and of conserving the serum for children under 3 years of age. In the Syracuse work Drs. Ruhland and Silverman⁴ made an additional point of some importance in stressing the value of early diagnosis. When the serum is given during the first four days after exposure, the proportion of patients who are completely protected is greater than when the serum is given in the second four days. True, the difference is not great and if serum is given in the first week the measles attack will, in any case, be 'modified'. True, also, some authorities believe that it is desirable to modify the attack rather than to prevent it altogether, so as to confer on the patient a more or less lasting immunity. But it must not be forgotten that, as the delay in giving serum increases, so also must the dose increase. The remedy is so precious that this point cannot be overlooked. Early diagnosis means early attention for the patient as well as for the contacts, and this must materially affect the prognosis. As a result of their publicity campaign, calling attention to the possible significance of malaise, slight fever and catarrhal symptoms, Ruhland and Silverman were able to show that in nearly 90 per cent of cases a physician was called on or before the fourth day of illness. Obviously, if physicians are to see patients so frequently in the pre-eruptive stage of the disease, early specific signs become of increasing importance. The appearance of a 'measles line' (a line of congestion across the conjunctiva of the lower lid) shortly after the onset of fever has been described by Stimson.⁵ Still more recently, Wadsworth and Misenheimer⁶ have reported that, by the use of ultra-violet rays, the rash itself may be detected for from thirty-three to seventy-six hours before it becomes visible by ordinary light. It may be hoped that, as the attention of the

pre-eruptive stage, still further aids to confident diagnosis will be forthcoming." *J Am M Ass*, 1928 vii 176)

A TEST FOR PREGNANCY

"All will agree with Dr. A. C. Siddall* that a simple and satisfactory test for the presence or absence of pregnancy would be most valuable, not only to the obstetrician, but also to every general practitioner. He remarks that at present perhaps the best known test for pregnancy is that of Abderhalden, but he agrees with Smith and Shipley, who tried to bring it within the realm of practicability, and concluded that it is of no value for the diagnosis of pregnancy. He mentions the verdict of De Lee that the epinephrine glycosuria test, Kammtz's phloridzin test, the dextrose test, and Fahraeus's red blood cell precipitation test are merely of academic interest, and also the statement of Hunt and Long that no laboratory method has yet been devised which is absolutely and infallibly diagnostic of the presence or absence of pregnancy, with the exception of radiological examination in the later months. Experimental work in this field has been hitherto dominated by two ideas—namely, that pregnancy causes a specific protein (ferment) to appear in the maternal blood, and that during the early months of gestation there is a tendency to glycosuria. Siddall suggests a test, however, which is based on a different idea from these. Early in 1926 he advanced the hypothesis that if the enlargement of the uterus and breasts of a pregnant woman is due to the presence of a hormone in the circulation, then corresponding changes should occur in the uterus and breasts of a test animal which had received injections of blood from the pregnant female, whereas the blood from non-pregnant women should give negative results. Binz, in 1924, had observed that, after injecting female mice with the blood of pregnant women, a transverse enlargement of the mouse's uterus resulted, and this result was confirmed towards the end of 1926 by Trivino and Fels. Franck and his co-workers, in a series of papers dating from 1926, have also demonstrated the presence of the female sex hormone

* A. C. Siddall. A Suggested Test for Pregnancy, based on the Action of Gravid Female Blood Serum on Mouse Uterus. Preliminary Report. *J Am M Ass*, February 4, 1928.

in the enucleation, not only during pregnancy, but also during the menstrual periods. These results seem to indicate that the blood of non-pregnant females might also have some effect on the uterus of the test animals. Siddall's observations, however, show that this is so small as not to invalidate his method as a test for pregnancy. His test animals were immature non-castrated virgin female white mice of less than 20,000 mg weight. One cubic centimetre of the patient's blood serum is injected subcutaneously into an immature virgin white mouse once daily for four or five days. On the sixth day the animal is killed, the weight of the mouse is divided by the weight of the uterus *plus* ovaries, and the resulting ratio provides the criterion for a positive or negative conclusion, a ratio below 400 being positive and a ratio above 400 being negative for pregnancy. Fifty-seven patients were submitted to this test, of twenty-six pregnant patients, twenty-five gave a positive mouse test, while of nineteen non-pregnant patients eighteen gave a negative mouse test, and twelve were incomplete cases. Such evidence requires confirmation in a larger series of patients with controls, and it is to be hoped that further information will be forthcoming" (*Brit M J*, 1928, 1, 952).

NORMAL WEIGHT AND WORKING EFFICIENCY

By MAY R. MAYERS, M.D.

"The maintenance of a normal weight is one of the best indications of good health. A healthy worker is an efficient worker and one who is less liable to meet with accidents. Have you weighed yourself recently, and compared your weight with the normal weight for your age and height? If not, you should do so at once. Indeed, you should do this every six months at least for your weight is in many ways an excellent indication of your state of health. If you are more than ten pounds heavier than you should be for your age and height you should do something about it—and the sooner the better. Persons who are overweight are more subject to diabetes, kidney trouble, high blood pressure and many other diseases than other people. Also the necessity for carrying about the excessive weight is a constant and unnecessary strain upon the heart. It is very important that you do not weigh too much.

The very best way to reduce is to get more exercise. This increases the number of calories which your body expends during the day, and frequently if one gets enough exercise, one can reduce without limiting one's diet at all. In order to lose weight, the expenditure of calories by the body must be greater than the number of calories supplied to the body in the form of

food. Consequently, in many cases, it is quite sufficient to increase the amount of exercise which one takes, and eat a perfectly normal diet in order to reduce. In the case of those whose work is essentially physical, it is not desirable that the exercise be further increased. Such persons, if they are more than ten pounds overweight should restrict the number of calories in their daily intake of food. They are eating too much for them. Each person is a law unto himself. What is too much food for one person may be insufficient for another. Each person must work out the question for himself, and find out what his individual needs in this direction are.

For those who require less food, it is usually best to restrict the number of calories per day to from 1,400 to 1,500. But remember that your diet must at all times be a balanced one. In selecting your day's menu follow the general principles which have already been explained to you. These principles apply quite as well to a reducing diet as they do to a normal diet. You should have plenty of fruit and vegetables. These are relatively low in calories and you can eat a great deal of this type of food without eating too many calories. Have at least two glasses of milk a day, regardless of anything else. These foods will in a general way supply you with all of the salts and vitamins which you require. Then fill in the remainder of your 1,400 or 1,500 calories in any way that you wish. It does not make any difference whether you eat fattening foods like bread and butter and potatoes or not, provided your *total* number of calories is not too high.

Much is said about foods which are fattening and foods which are not fattening. All foods are fattening if you eat too much. No single food will make you fat if the total number of calories in your food for the day is not too high for your personal requirements. One of the greatest dangers of reducing is the fact that when people reduce they usually eat a diet lacking in the important elements—particularly the salts and vitamins. A diet such as suggested above will protect you from committing this mistake. You will reduce on it, but you will feel well at the same time. This is not always the case at the present time with people who are "dieting" to reduce.

Remember also that it is not wise to lose weight too rapidly. You should not lose more than two pounds a week. If you are losing more rapidly, it is a sign that you should eat more. If you are not losing at all on such a regime you should consult a physician. Do not use medicine or baths to reduce unless under supervision. These may run you down if you do not succeed in reducing. Your regime your case is one of the many. Your glandular make-up is. Only a physician can handle

The following menus will show you that you can have attractive and inexpensive meals, and plenty to eat and yet reduce—because you will not be eating more than 1,400 calories of food per day. These menus are merely suggestive however. You can make up any number of additional ones yourself by putting together 14 or 15 of the 100 calorie portions listed in the *Industrial Hygiene Bulletin* for June, 1926.

Sample Diets for Reducing

1,400—1,500 CALORIES

DIET No 1

Breakfast

	Number of Calories
$\frac{1}{2}$ grapefruit and sugar	150
1 roll	100
1 pat of butter	100
Coffee with cream and sugar	100

Lunch

Lettuce and tomato salad	100
1 slice of bread	100
$\frac{1}{2}$ pat of butter	50
Tea with sugar	50

Dinner

Chicken, small portion	100
Gravy	50
Cooked vegetables, average portion	100
Small potato	100
1 slice bread	100
1 pat butter	100
1 glass of milk	80

Total 1380

DIET No 2

Breakfast

Juice of one small orange	70
1 egg	100
1 glass of milk	80
1 roll	100
$\frac{1}{2}$ pat butter	50

Lunch

Cream cheese, 1 tablespoonful	100
Crackers (3)	100
Jello (usual portion)	100
Iced tea with sugar	50

Dinner

Roast lamb, ordinary portion	200
Small potato	100
Peas, ordinary portion	100
Small piece of pie or cake	100
Fruit, salad, 1 teaspoon French dressing	150
Coffee with cream and sugar	100

Total 1500"

PROFESSIONAL DISCIPLINE

"Much interest has been aroused in Alberta in the Professional Discipline Act passed at the recent session of the legislature. Whatever else may be said, it undoubtedly has the distinction of originality, as no similar legislation has prob-

ably ever been enacted in any part of the English speaking world.

The Act sets up a Board, none of the members of which need be a professional man, which has very extensive disciplinary powers over the practitioners of any profession or calling listed in the schedule to the Act. The Board has power to act as a court of appeal from the decisions of the governing bodies of the professions concerned, and has also authority to originate proceedings. It can make its own definitions of professional misconduct and is not to be bound by established rules of evidence. Needless to say, the introduction of the bill caused a storm of protest from the legal, medical and dental professions, all of which passed very strongly worded resolutions denouncing it as an unjustifiable discrimination against the members of the professions concerned. Particular objection was taken to a clause which prevented any appeal to the courts from the decision of the Board. The Government yielded to representations on this point and struck out the section, but when the bill made its final appearance in the House, it was found that the same result had been achieved by adding to another section a few words which declared that the decision of the Board should be final. The schedule to the Act has been left blank, so that up to the present it is inoperative. At any time, however, the Government may, by order-in-council, apply it to any profession or calling it desires.

The consensus of legal opinion in the province is that the legislature, in its desire to put teeth into the act, has over-reached itself and defeated its own ends. One section provides that in all matters within its jurisdiction, the Board shall have all the rights and powers of the Supreme Court of Alberta. It is contended that this constitutes the Board a court and its members judges, and that, as judges can only be appointed by Ottawa, the appointment of the Board by Edmonton is unconstitutional. If the act is brought into operation, this question will doubtless be fought through to the Privy Council.

* * *

The Act described by our correspondent has caused more than a local stir amongst members of professions concerned, and if or when it is applied, it will probably attract even wider notice.

We might add here that there have been no grounds of complaint against professional governing bodies on the score of laxity or excessive leniency. In a remarkably large number of cases handled by them in the past, appeals to the courts have been successful and both doctors and lawyers have felt that the judges have been too lenient. As a result of this, the branches of the Law Society, during the recent session, secured amendments to the Legi-

fession Act, which allow an appeal to the courts from a decision of the branches in matters of discipline only when the branches have not been unanimous. Rightly or wrongly, the feeling

does exist that the courts have been too lenient towards offending members of the learned professions" (Supplement to the *McGill News*, 1928, ix, 3)

Abstracts from Current Literature

MEDICINE

Recent Changes in Our Views Concerning Diseases of the Lungs Myers, J A, *Minnesota Med*, 1928, xi, 465

The diagnosis of diseases of the chest has undergone many changes in the last few decades, due largely to the aid of the x-ray and the laboratory. In addition to these, however, we have also learnt more regarding physical signs. We now recognize a definite relationship between rigidity or atrophy of the chest muscles and disease of the lungs. The anatomy of the upper part of the chest is being taken into account, especially the differences between the two sides as regards the relations of various structures to the apices, the right apex, for example, comes into direct contact with the trachea, whilst on the left side the subclavian artery intervenes. Again, there is usually a slightly heightened percussion note over the right apex because the superior vena cava and right innominate vein lie in front of the medial part of the apex, this also accounts for increased tactile fremitus, increased transmission of whispering and a broncho-vesicular type of breath sounds on this side.

The failure to consider these facts probably accounts for the belief that the right apex is more often affected with tuberculosis than the left, Dr Myers thinks that if steroscopic films were taken in a sufficiently large series of cases it would be found that one side was not more liable to infection than the other.

Perhaps the most valuable development in auscultatory examination is the method of eliciting râles by having the patient take a deep breath, exhale, and then just at the end of expiration cough and inhale deeply. This will bring out râles which are otherwise not detectable.

The x-ray, amongst its many other advantages, has told us much about the healing of even advanced tuberculosis of which we were formerly ignorant. It also has shown us that definite areas of pneumonia may appear and disappear in a few days without the manifestations on which we are apt to become dependent. The x-ray examination in Dr Myer's opinion "must be regarded as part of the general examination and as such we are compelled to recognize it as second only to the finding of

tubercle bacilli." It is indispensable in the diagnosis of tuberculosis of the tracheo-bronchial glands in children.

On the laboratory side we have learnt that there are numerous non-pathogenic acid-fast bacilli which may be mistaken for tubercle bacilli. One negative sputum examination means nothing, the bacilli may be found after fifty successive negative examinations. It must be remembered that much sputum may be swallowed, especially in the case of women and children, and the stomach contents and stools should therefore be examined also. Injection of a guinea-pig should be resorted to on occasion. Other pathogenic organisms should always be sought for as well.

Some obscure cases may be immediately cleared up by a bronchoscopic examination, such, for instance, as small tumours projecting into a bronchus, stenosis of the bronchus, and foreign objects not detected by the x-ray. Then the injection of iodized oil has come to the front both for diagnosis and treatment. There are signs that a more balanced view is being taken regarding its employment, particularly since it has been shown that the oil may remain in the lung over long periods.

Perhaps the greatest number of mistakes in diagnosis of pulmonary disease are due to our not making careful systematic examinations on all patients, no matter how trifling the symptoms may be. And yet it is the patient whose disease is soonest detected in whom treatment is most effective.

H E MACDERMOT

Post Encephalitis and Its Problems Parsons, A C, *Proc Roy Soc Med*, 1928, xxi, 8.

It is only ten years ago that encephalitis lethargica began to be recognized in Great Britain as an inflammatory disease of the brain, sometimes acute, at other times subacute or chronic, prolific in its manifestations, disabling if not fatal in its results, difficult to diagnose and almost defiant as to treatment and prognosis. Something has been learnt of its epidemiology but the way in which it has spread and its relatively high incidence in Great Britain are still unexplained. Its cause is unknown, and attention is now being chiefly focussed upon the consequences and how to deal with those disabled by it, since no effective treatment of the

disease has been discovered. It is true that it accounts for less ill health and disablement among the population than does influenza, for example, or measles, or venereal disease, but in proportion to the few attacked it probably has a higher disablement and death rate than any other disease except cerebro-spinal meningitis. The death rate is calculated to be between 35 and 40 per cent, and as far as can be determined, about 40 per cent of the patients become disabled in some degree.

A broad classification of sufferers from the after effects of encephalitis shows the following three groups: (a) those suffering mainly from physical sequels, such as the very frequent Parkinsonian syndrome, (b) those who chiefly show mental deterioration (and it is probable that the mental processes are affected in all cases, either in the primary attack or subsequently), (c) those exhibiting demoralizations, or changes in conduct, results which are especially common in children.

The problem now is to deal with these disabilities, suitable institutional accommodation must be provided for the progressive physical disabilities (which are often combined with mental failing) and there should be general re-training and education of the youngest children, and training and control of adolescents with serious character changes.

The paper should be referred to for full details of these post-encephalitic disorders and the way in which local administrative bodies have dealt with them in England.

H. E. MACDERMOT

Bact Abortus Bang als Erreger septischer Erkrankungen beim Menschen (Bact Abortus of Bang as the Cause of Septic Infection in Man.) Habs, H., *Zeitschr f Klin Med*, 1928, cviii, 445.

The author reports in detail four cases of generalized (septic) infection in man with *Br Abortus*, in all of which the diagnosis was confirmed by agglutination tests, and in one case by blood culture as well. In the first case the patient was under observation at intervals for six months. The symptoms were inconclusive and the tentative diagnosis was typhoid fever.

In the second case the evidence of severe generalized infection with a subjective sense of well-being, a good general condition, and the experience gained in the first case, aroused the suspicion of *Br Abortus* infection.

In the third case, there was a long continued fever of intermittent type, the physical examination of the various organs was negative, the blood picture showed a leucocytosis of 7,800 per c mm., with 46 per cent of lymphocytes, there were no signs of distress even when the temperature was elevated, and the Widal test was negative. All this suggested infection with *Br Abortus*.

The fourth case showed few physical signs beyond fever of an undulating type, with slight enlargement of the spleen. There was a sense of well-being and a good general condition quite out of proportion to the degree of infection.

The source of infection was not determined, but probably was from milk.

Infection with *Br Abortus* bears a general resemblance to typhoid fever. The following signs should suggest this diagnosis: a prolonged fever of intermittent or undulant type, an only moderately increased pulse rate, slight splenic tumour, a clear mental state, a normal or diminished leucocyte count with relative lymphocytosis, and a negative Widal test. The diagnosis will be clinched by positive agglutination tests with *Br Abortus* or by a positive finding in the blood culture.

A. G. NICHOLLS

Hyperthyroidism and Diabetes John, H. J., *Am J M Sc*, 1928, clxxv, 741.

In a series of 3,335 cases of hyperthyroidism the author found non-physiological hyperglycæmia 285 times. In this series 150 glucose-tolerance tests were done. These varied from normal to those of the most severe type of diabetes. But there is no direct relationship between the glucose tolerance and the degree of hyperthyroidism, therefore the lowered glucose tolerance cannot be due to some toxic effect of the thyroid secretion.

It has been shown that the liver is practically free from glycogen in cases of hyperthyroidism, there must be some interference with the storage of glycogen which is accomplished through the influence of insulin, therefore the lack of glycogen storage indicates a shortage of insulin.

What happens to those patients who show a decreased tolerance? Even after thyroidectomy many of them must follow a dietary regimen, while in others improvement occurs without any dietary observance, but the glucose tolerance curves show that these patients are not normal even after operation. Apparently the damage wrought in the islands of Langerhans is permanent.

LILLIAN A. CHASE

Diabetes and Hyperthyroidism Joslin, E. P., and Lahey, F. H., *Am J M Sc*, 1928, clxxvi, 1.

The similarity between severe, untreated diabetes and hyperthyroidism is shown by the loss of weight, red cheeks, high metabolism, increased pulse rate, and the weakness rather than strength from the high calories consumed. The series here presented includes 75 cases. Complete recovery has not taken place in any case in this series.

The authors have raised the standard for diagnosis of diabetes in hyperthyroidism to a

blood sugar of 0.15 per cent fasting or 0.20 per cent or more after meals, in addition to glycosuria. The same diabetic family tendency was in evidence as a cause of diabetes in this group as in the conventional diabetes. In 85 per cent of the exophthalmic goitre cases the hyperthyroidism preceded the diabetes.

The authors conclude that surgery greatly ameliorates the condition of these patients, that the treatment of the diabetes in the presence of hyperthyroidism must be adapted to the increased metabolism, and gradual and moderate changes in diet and insulin should be carried out, since the tendency of the ordinary diabetic and the ordinary thyroid case is to do well. The 75 cases were not cured of their diabetes after successful operation on their thyroids but the majority were improved to an unusual degree. The hyperthyroid patient from physiological, pathological, and statistical evidence is somewhat more prone to diabetes than the ordinary individual, and for the remainder of his life should be so regarded, whether operated on or not.

LILLIAN A. CHASE

Hæmoglobin Construction Within the Body as Influenced by Diet Factors Whipple, G. H. *Am J M Sc*, 1928, *clxxv*, 721

Red muscle pigment can be isolated from striated muscle tissue and tested chemically in the living animal. There is biological evidence that muscle hæmoglobin and blood hæmoglobin of the dog are distinct substances, though they are almost indistinguishable by modern methods of examination. As a general rule the content of muscle hæmoglobin in striated muscle depends largely on work demand and exercise.

Short anæmia periods will not show any corresponding change in the level of muscle hæmoglobin. Long continued, severe, experimental anæmia may lower the muscle hæmoglobin which is not subject to rapid fluctuations. Muscle hæmoglobin is influenced by diet but the change is very slow and cannot be demonstrated in pups with less than fifteen weeks diet control. After fifteen to thirty weeks there is a manifest difference in the pup fed standard bread and the litter mate fed standard bread plus equal parts of cooked liver.

Breadstuffs and the common grains as well as dairy products are least potent of any diet factors, as measured by their capacity to promote hæmoglobin regeneration in the normal anæmic dog. Skeletal muscle varies widely in its capacity to produce new hæmoglobin. Heart muscle as a whole is a little more potent than skeletal muscle, chicken gizzard is potent. Fish is as unregenerative of hæmoglobin as bread and milk. The green leafy vegetables are popularly overrated. They have little power to help in forming hæmoglobin.

Liver is at the top of the list of favourable diet factors. Kidney stands next to liver. Hæmoglobin set free in the blood stream will not escape through the kidney until a certain concentration of hæmoglobin in the blood stream is reached.

Bone marrow, spleen, brain, and pancreas are rated about the same. They are one-third to one-quarter as potent as liver. Fruits are of extraordinary interest, because some of them are quite potent and others meagre. Apricots are high and raspberries are low.

Iron by mouth will produce a favourable reaction if there exists an iron shortage in the body, but iron plus liver gave the expected liver reaction superimposed on the iron reaction. During periods of rapid growth the anæmic dog will show a decrease of hæmoglobin production.

In the study of anæmias attention has been focused on hypothetical toxins which were supposed to destroy red cells *in vivo* and thus bring about anæmia. The author's view is that there is a large group of anæmias due to *lack of something*. Is pernicious anæmia due to lack of stroma building material but a great excess of all sorts of pigment and pigment building material? Pernicious anæmia may prove to be a deficiency disease.

LILLIAN A. CHASE

Fever in Gastric and in Duodenal Ulcer Bang, S., *Arch Int Med*, 1928, *xl*, 808

The writer states that the presence of fever in cases of peptic ulcer has not received due recognition and that, when described, its occurrence is frequently related to hæmorrhage. He analyses 386 cases and points out that while fever does occur in cases which bleed this relation is not causal. Fever is also present with non-bleeding ulcers, and the presence of large amounts of blood in the gastro-intestinal tract may possibly cause slight elevation of temperature or increase of pre-existing fever, but does not, *per se* account for the febrile course of 87.5 per cent of his series of peptic ulcer cases. The influence of the grade of anæmia and the "violence" of the hæmorrhage is also discussed and these are discarded as primary causes of fever.

It is noted that fever is more prone to occur in early acute, or rapidly progressing ulcers than in older, more chronic lesions. The extent of this fever is shown by charts to vary from 0.8° to 2.2° C above normal, and in one case to persist as a remittent and intermittent rise for 96 days.

Particular attention is drawn to the work of Askanazy, Konjetzky, and Kalima who have emphasized the acute inflammatory manifestations in and about the gastric and duodenal lesions, and the presence in the ulcer-bearing

areas of a greater or less degree of gastritis which may even precede the actual rupture of the mucosa. From this is drawn the suggestion that local or general gastritis and duodenitis is a frequent concomitant, and possibly precursor, of peptic ulcer, and that during this process a characteristic fever is exhibited.

J. B. ROSS

Treatment of Diphtheria Carriers Harvey, W. C., *Lancet*, 1928, ii, 58

All diphtheria carriers from the Metropolitan Asylums Board Infectious Disease Hospitals were collected in one hospital, and a study made, primarily to ascertain the cause of continued harbouring of infection. All cases had been definite "carriers" for a period of at least twelve weeks, and no case was considered as cured until six cultures taken at weekly intervals showed negative results.

It was found that the diphtheria organism maintained its existence chiefly in those respiratory passages which were the seat of pathological or other abnormal processes, and that the bacilli were saprophytic in the inflammatory products and did not exist in living tissues.

Regarding treatment, the carriers with bacilli in the throat only were cured by tonsillectomy and adenoidectomy in almost 100 per cent of cases, the time of operation being set at six to eight weeks after the onset of disease, earlier than is usually advised. "Nasal carriers" were much more refractory and treatment both more prolonged and less successful. Autogenous vaccine therapy proved disappointing. Nasal douches twice daily gave the best results, in some cases combined with vaccine courses. In all, 78 per cent of cures resulted in nasal carriers.

The antrum of Highmore was suspected in chronic resistant cases, and in two bacilli were recovered from the sinus at operation. X-rays did not help in the diagnosis. Removal of adenoids alone was ineffective in nasal carriers.

The presence of virulent diphtheria bacilli in the ear was found to be uncommon but such cases were most resistant to treatment. Most ear infections were with diphtheroid organisms. The general health of the majority of carriers was excellent and seemed to play a small rôle in treatment. Greatest emphasis is laid upon removal of all collections of purulent and necrotic material in all forms of treatment.

J. B. ROSS

Action Nocive des Vapeurs de Formol (Noxious Action of Formalin Vapour) Sabrazès, J., and Pennanéach, J., *Comptes rend de séances de biol de Bordeaux*, 1928, viii, 241

The authors draw attention to the dangerous action of formalin inhalation and the necessity

of protecting exposed persons from its effects, and report the direct proof obtained by them of the toxicity of formalin vapour. They chose the cobra for this purpose and exposed it in a confined atmosphere to formalized air for one hour daily. Animals so treated died in three months. Control animals were killed the same day and the tissues of both examined. In the exposed cobra, the mucosa of the pituitary was found to be swollen and covered with mucus, and denuded of cilia, and that lining the trachea and bronchi was metaplastic, with vacuolated pyknotic cells and amorphous areas, and the wandering cells, lymphocytes, deep epithelial elements, and cilia absent, collagen and elastic tissue were increased, all vessels greatly engorged, the lungs were congested, cedematous and emphysematous, the liver, spleen and kidneys showed advanced stasis and degeneration. Similar, though less advanced, changes were seen in cobras left in the open air but in which some formalin vapour had been introduced. Further studies are being made on the changes produced by formalin vapour in the blood and hæmopoietic organs.

In view of these facts the authors suggest using, in the colour preservation of specimens, a substitute for Kaiseiling solution No. 1 (which contains 15 per cent formalin) of two parts per 1,000 of "chloramine sodique du toluène," and then restoring the colours by passing through alcohol and into Kaiseiling's solution No. III. Persons exposed to formal vapour in operating rooms or laboratories should wear a surgical mask which contains a sachet soaked with weak ammonia water or acid tartrate of ammonia or better still, with 8 per cent solution of borax in 10 volumes of water.

M. E. ABBOTT

An Ideal Medical Museum Delavan, D. B., *Med J & Rec*, June 20, 1928

This paper is a strong plea for the establishment of a central medical museum on much broader lines than those already existing. Dr. Delavan points out that most medical museums are narrow in scope, and, in the main, are designed to take care of undergraduate instruction. He remarks "we have few medical museums of recognized superiority." Among the three notable exceptions to his general criticism is the Pathological Museum of McGill University. From data that have been accumulated by the International Association of Medical Museums, it appears that the existing museums in Europe devote themselves to one or more of the following departments, anatomy, comparative anatomy, veterinary anatomy, anthropology, biology, bacteriology, physiology, pathology, microscopy, medical chemistry, medical toxicology, materia medica, pharmacology, surgery, and climatology. Dr. Delavan

injections were given if the temperature was still high, if the patient was still toxic or if peristalsis had not been resumed. They conclude that there is enough evidence to warrant the use of this serum in cases of acute intestinal obstruction and peritonitis associated with toxæmia.

H. E. MACDERMOT

Glucose and Insulin in the Treatment of Shock

Levy, W. E. and Maclean, Henry, *Current Researches in Anæsthesia and Analgesia*, 1928, May-June, p. 161

In shock the liver tissue is specially affected. There is interference with the metabolism of carbohydrates and with the storage of glycogen. A damaged liver is the prime factor in producing a state of acidosis, a condition in which the fats are not completely burned, as indicated by a low carbon dioxide combining power and the presence of acetone and diacetic acid in the urine. The author in his treatment of shock gives, very slowly, 1,000 c.c. of a 10 per cent glucose solution by intravenous injection. He takes from one and a half to two hours to administer the whole amount. When one-third of the glucose solution has entered the vein he gives one-third of the total estimated dose of insulin subcutaneously. He estimates the dosage of insulin by allowing one unit for each gram of glucose. When the second third of the glucose solution has been given insulin is again

injected. The final third of the insulin is given at the end of the injection.

The action of the insulin is probably two-fold, first, in permitting the entire consumption in the body, of the glucose (as shown by the absence of sugar and acetone in the urine shortly afterwards) thereby combating the acidosis, second, by enabling the tissues to hold fluids, which otherwise would have been excreted by the kidneys, as a result of their stimulation by free glucose.

W. B. HOWELL

Treatment of Tuberculous Peritonitis by Ether

Anæsthesia. Savage, W. E., *Current Researches in Anæsthesia and Analgesia*, 1928, May-June, p. 137

Many theories have been advanced to explain the cure of tuberculous peritonitis after an operation which has consisted in nothing more than opening and closing the abdomen. It occurred to the author that the cure might be due to the anæsthetic. Since March, 1915, he has treated seven cases of tuberculous peritonitis by ether anæsthesia alone. Of this number six recovered and one showed no improvement. The writer attributes the one failure to the fact that the disease had reached the stage of caseation. The tuberculosis having become non-vascular there was no means by which the ether in the blood could reach the foci of the disease.

W. B. HOWELL

Obituaries

He scarce had need to doff his pride or slough the dross
of earth,
E'en as he trod that day to God so walked he from his
birth,
In simpleness and gentleness and honour and clean
mirth

Beyond the loom of the last lone star, through open
darkness hurled
Farther than rebel comet dared or living star swarm
swirled,
Sits he with those that praise our God for that they
served His world

RICHARD BARRINGTON, NEVITT

AN APPRECIATION

On May 11, 1928, there "went over to the majority" a citizen and a medical practitioner whom the people honoured with one acclaim, and now mourn over as a common loss, a gentleman of the old school, and a dearly beloved doctor, whose like we shall not look upon again. He passed peacefully to his reward sitting in his chair, without sign of suffering or of struggle, his pipe laid carefully down on the table beside him, and his hands folded before him, as sinking to the sleep of the just he "passed to where beyond these voices there is the peace and rest that remaineth."

Born in Savannah, U.S.A., on November 22, 1850, he had completed a little more than half of his seventy-eighth year, and so was ripe for Time's sickle though by no means decrepit in mind or body. Shakespeare has

told us that "men must endure their going hence even as their coming hither, ripeness is all." It chanced that he came to "school age," that pregnant time of leisure, in the midst of the fratricidal strife known to history as the "War of the Secession," and was compelled to seek friendly shelter and opportunity of learning within the Canadian border line, and so in 1865 he became a student at Bishop's College, Lennoxville. Here he diligently applied himself to the tasks of peace until he was able in 1868 to matriculate in the University of Trinity College, Toronto. His further progress in that seat of higher learning is sufficiently indicated in this abbreviated form, B.A., 1871, M.B., 1874, M.D., 1882. In the latter half of his medical undergraduate ship he lived in the General Hospital, at first as a dresser, then as assistant apothecary, and finally as house surgeon, serving both in patients and out patients. This was a clinical opportunity of inestimable advantage, comparable to the old time apprenticeship in making practical practitioners. In the summer or autumn of 1874 he received the appointment of surgeon to the now famous North West Mounted Police, and proceeded to Fort McLeod, by way of Pembina and Winnipeg, one thousand miles on horseback, to join Colonel McLeod, and the incomparable force which he commanded, a force which has covered itself with a cloak of romance, as carrying and dispensing the King's justice "from sea to sea, and from the river (St. Lawrence) to the ends of the earth."

Amid this band of heroes he was no laggard, but did his duty fully with the best. His experience differed somewhat from that of his comrades, for he was ex-

pected to exercise his art among the aborigines whose camps came within his reach. These experiences, as detailed in his diaries, throw much light upon the habits and superstitions of the natural Indian, and would at that time instil into the savage mind new ideas of "the medicine man," so deft was he in many ways and specially in his handling of difficult parturition. Naturally, he worked singlehanded and had to fulfil many functions simultaneously, but these poor benighted people were treated with the same consideration and regard as would be manifested in civilized surroundings. He was throughout his life always most modest and retiring, though strong in will and inflexible in purpose.

He returned to Toronto in 1878 and began a civil practice which was only abandoned on the day of his

Richard Barrington Nevitt

death, in obedience to the imperious summons for duty elsewhere, for as Tennyson said of the Iron Duke, "There must be other nobler work to do, than when he fought at Waterloo, and victor he must ever be."

Immediately on returning to practise in this city, he set himself with his accustomed courageous vigour to carve out for himself, without powerful friends and influence, a successful career, and shortly became one of the most widely known practitioners of the city. While cultivating his surgical instincts and proclivities, he carried on for years an obstetric, gynaecological and general practice, which involved, on an average, a birth a day, a performance perhaps only equalled in extent by the records of the elder Dr James Ross, and Dr Jerrold Douglas Ball. It is to be noted, however, that these latter did no hospital or teaching work as did Dr Nevitt so persistently in his long and active association with the House of Providence, the Children's and the General Hospitals, and, more particularly perhaps, with St Michael's Hospital from its beginning. Dr Nevitt had a good clinical instinct, a trained mind, and a deft hand. The classic lore acquired at Trinity from the accomplished John Ambery was never laid aside, and many a student has reaped enjoyment from the sowings of that excellent son of Brasenose.

Perhaps the association through which Dr Nevitt will be longest remembered will be his active connection

with the Women's Medical College in Toronto. To Dr Michael Barrett, of pious memory, the resident medical officer of Upper Canada College, successful teacher there of classics, anatomy, physiology and chemistry, and professor of physiology at the Toronto School of Medicine, is given the credit of establishing this school in 1883. On his first association with the college Dr Nevitt occupied the Chair of Sanitary Science, but in 1887, after Dr Barrett's sudden demise, there was a readjustment and Dr Nevitt assumed the Chair of Surgery. Dr McPhedran was at the time elected Dean, but retained office for a very short time, and was at once succeeded by Dr Nevitt, who continued to preside over the destinies of the school until the amalgamation of Trinity with Toronto's medical faculty in 1906, at which time the question of co-education in medicine was also settled. He retired from active teaching life with the disappearance of the Women's College, but retained his interests in the corporation of this institution and also in that of Trinity, and continued his duties at the Women's Hospital and Dispensary while still keeping up his surgeoncy at St Michael's Hospital.

Dr Nevitt was a member of the Academy of Medicine from its inception, and a member of the Ontario and Canadian Medical Associations, he was also an active associate of the Toronto Medical Society and of the Library Association. Shortly before his death the Academy made him an honorary member *in perpetuum*.

Dr Nevitt's father was Mr John Wilson Nevitt, a merchant of Savannah, and his mother was Miss Mary Tschudi of Alsace and Philadelphia. He married Miss Elizabeth Ellen Beaty, elder daughter of Mr Robert Beaty of "The Leader," who died about nine months ago.

Doctor and Mrs Nevitt have left issue surviving them, two sons, Irving H. C. Nevitt and Richard Nevitt, and two daughters, Mrs George Egerton Byerson and Mrs Davidson Black. One son, the Rev Barrington Nevitt, died in 1918, and another son, Bertram, was killed in action at Courcellette in 1916.

Requiescent omnes, permultis ille bonus flebilis ultimus occidit. In eternam pacem emigravit.

IRVING H. CAMERON

Dr C. M. Anderson, Director of Provincial Laboratories, Department of Health, died suddenly on July 18th, at the summer home of his father in law, Mr James Firth, Burritt's Rapids, Ontario.

Dr Anderson was in his thirty-ninth year. He was born in Ottawa and received his preparatory education in that city. He graduated from McGill University in 1915 with the degree of M.D., C.M. Immediately following his graduation he engaged in laboratory work at the Royal Victoria Hospital, Montreal, and following this he proceeded overseas as Captain in the Royal Army Medical Corps, where he served with distinction in the Field Ambulance Service. Upon his return to Ottawa he served on the staff of the Department of Soldiers' Civil Reestablishment, and then in 1920 he attended the School of Hygiene at Johns Hopkins University, Baltimore, and received the Diploma of Public Health from this institution.

On the completion of his public health course he was appointed Bacteriologist to the Provincial Department of Health and in this position he so distinguished himself that in 1923 he was appointed Director of Laboratories, succeeding Mr H. M. Lancaster, who is now Chief Chemist of the Federal Department of Health, Ottawa. Dr Anderson in his position in the Department of Health was an able administrator and most efficient director, always doing his utmost to give the maximum service to the medical profession and public in the province. He is survived by his wife and two young daughters, now residing in Ottawa.

Dr Hector Bonner, who graduated from Trinity in 1877, died in Toronto late in June. Dr Bonner had been surgeon in the North West Mounted Police, going to the Yukon in 1897, and while there was successful in locating some valuable claims. Returning to Toronto, Dr Bonner began again to practise, though at an advanced age, and for the last eight years he had kept at work until failing health necessitated his going to the Hamilton Sanitarium where he resided until his death. A man of many interests, Dr Bonner had concerned himself with politics as well as with medicine and prospecting, and had been a Liberal candidate in both the provincial and federal Houses.

Dr Henri Alfred Archambault, a physician of many years' standing in Montreal, died at his home, 111 Grand Boulevard, Notre Dame de Grace, on July 29, 1928, at the age of 76. Dr Archambault was born in L'Assomption, and was educated in the local schools and, later, at Victoria College, where he studied medicine. He graduated from this medical school in 1883 and took up the practice of his profession in Montreal. For many years his office was on St. Louis Square. Later, Dr Archambault was appointed Surgeon major to the 65th Battalion, and he served with this regiment for a long period. He was also for a time physician to the old Montreal jail, and a great many of the prisoners passed through his hands at various times. Some years ago failing health necessitated his retirement and for the past year he has been seriously ill.

Dr James Stanley Chisholm. The death of Dr James Stanley Chisholm, of Mahone, Nova Scotia, occurred at the Homewood Sanitarium, Guelph, Ontario, on the twenty ninth of July.

Dr Chisholm had been convalescing from a nervous condition for which he had entered the Sanitarium, and his death was unexpected.

He was a son of Dr Murdoch Chisholm, of Halifax, who is very well known throughout Canada, and is a Past President of the Canadian Medical Association. After graduation in 1915 the deceased doctor enlisted for overseas service, and, shortly after his return, located at Mahone, where he quickly built up a large general practice, and established himself in the favour of the people.

Dr Wallace A. M. Dinwoody, one of the most promising of the younger medical men, died in the General Hospital, Toronto, on July 30th, as a result of hemorrhage from a duodenal ulcer.

Dr J. A. Dufresne passed away on July 25th, at his residence at Shawinigan. He had been in poor health for the last two years. Born at Deschambault in 1869, he studied at Three Rivers Seminary, Ste Anne de la Pocatière College, Quebec Little Seminary, and graduated as a physician at Laval University in 1895. He first practised medicine in his home town. In 1901 he moved over to Shawinigan Falls. He took at once a keen interest in the local politics of that newly born town and was in 1902 elected alderman. He was re-elected in 1904 and 1911. In 1920 he was elected by a large majority as mayor of Shawinigan Falls, and sat for eight years as the first magistrate of that fast growing city. He retired only in last July, on account of illness. In 1922 he was elected first

president of the Union of Canadian Municipalities, and as such the next year presided over its convention at Shawinigan Falls. The city council of Shawinigan Falls voted at a special meeting to give a civic funeral to Dr Dufresne, as the last tribute of the city whose citizen he has been for eight years.

Dr R. C. Ogilvie, formerly of Campbellford, Ont., whose death occurred on August 2nd, in Superior, Wis., after a long illness, was a graduate in medicine of the University of Toronto, who practised for some years in Port Hope, Mich., and later retired to enter the lumber business in the west.

Dr Allen B. Earle, a graduate of Queen's University in 1913, died in Hamilton on July 26th. Dr Earle served throughout the war in the Canadian Army Medical Corps, doing active front line work and receiving wounds from which he never completely recovered. He had taken post-graduate work in New York and London, and in his years in Hamilton had been devoting himself largely to surgery.

Dr Robert M. Goodwin, one of the most esteemed of the older practitioners of Manitoba, died very suddenly at his home in Carberry on July 26th. He had seemed to be in his usual health and good spirits on that day, had played a round of golf, and was ministering to a patient when he fell forward and expired almost immediately.

Graduating from Manitoba Medical College in 1894, he practised first in Elkhorn where he enjoyed a large following. Eight years ago he took up farming, but after two years resumed practice at McAuley, and in 1922 he moved to Carberry.

In his younger days he was a prominent athlete. He was a member of the United Church of Canada and was active in his Masonic lodge. He is survived by his widow and four children, one of whom, Dr Alex. M. Goodwin, is now in Edinburgh doing post graduate work.

Major Joseph W. Hunt, M.B., M.R.C.S., L.R.C.P. Following an illness of only a few days Dr J. W. Hunt, Clinical Specialist in the Division of Preventable Diseases of the Provincial Department of Health, passed away on Tuesday, July 24th, in the Toronto General Hospital, at the age of forty four years.

Born at Parry Sound and educated in Blind River and Albert College he received his medical degree from the University of Toronto in 1907. Following this he spent a year in London, England, where he continued his medical education and, upon return to Canada, settled in Sault Ste. Marie where he engaged in practice. Upon the outbreak of the War, Dr Hunt enlisted as medical officer, and served in France with great distinction until the close of hostilities. He was severely wounded during the year 1917. After serving on the medical staff of Christie Street Hospital for a year, he entered the service of the Provincial Department of Health in 1920 as Clinical Specialist, which position he held at the time of his death. His genial personality and unselfishness had made him a great favourite, and his loss will be deeply felt by his colleagues.

He is survived by his mother, Mrs. M. Hunt, and his sister, Miss Annie Hunt, both of Ridgeway, Ont., and his wife and three young children of this city. His burial was with full military honours.

News Items

BRITISH EMPIRE

The Council of the College of Surgeons of Australasia has decided to publish a journal. Its object is to assist the college in its aim to advance the science and art of surgery, and to encourage members of the medical profession to become efficient surgeons. It is felt that the publication of the new journal will not interfere with the usefulness of the *Medical Journal of Australia*, and that there will be ample scope for each.

History of Medicine in Wales

In connection with the recent meeting of the British Medical Association "an interesting little exhibition had been gathered together in the National Museum of Wales at Cardiff for the purpose of illustrating the history of medicine in the Principality, various manuscripts, charms, remedies, and other objects having been selected from the National Library, the National Museum, and the Cardiff Public Library. Specimens of "hydrophobia stones" were shown, these were composed of a kind of alabaster, and scrapings of them were mixed with milk and drunk by those who had been bitten by dogs and cats. The owner of one of these stones knew a man who, after a bite, about the year 1850, "meowed" like a cat, and was not relieved until he had received a dose of the medicine. The "Laws of Hywel Dda," in the tenth century, prescribed the status of the doctor, who was one of the officers of the royal household. He received his linen from the queen and his woollen cloth from the king. He had to attend all within the court gratuitously, except in certain emergencies, for which he received nuncence and his food, together with the "blood stained clothes" of his patient. His "sarhad" (in English "insult") was six line and sixpence in silver, his social value was estimated at six score and six line. One portion of the Laws dealt with the value of the members of the human body. Thus the value of a finger was one cow and twenty pence. The organs of generation were equal to one half of all the organs as also was the tongue, which must have rendered computation occasionally difficult after an aggravated assault. The exhibition included the text of the "Meddygon Myddfai," to which the President alluded in his address, containing the medical lore of the twelfth century physicians of Myddfai in Carmarthen shire. A fifteenth century manuscript on vellum consisted of a Latin translation of *Almansor*, a popular Arabic medical work. The manuscript showed very fine workmanship, being rubricated throughout, and with an illuminated capital letter at the beginning of each of the ten books. In connection with this exhibition at Cardiff it is interesting to note that the directors of the Wellcome Historical Medical Museum have announced the publication shortly of a book on the history and lore of Cymric medicine" (*Brit M J*, 1928, ii, 216).

Ferrier Memorial Fund

The contributors to the Ferrier Memorial Fund met on July 15th under the chairmanship of Sir Charles Sherrington, and resolved to invite the Royal Society to accept the sum of £1,000 in trust to found a David Ferrier Memorial Lecture. It was further decided that the balance of the fund shall be applied as seems best when the total contributions are known. The fund will be closed on September 30th. The honorary treasurer is Dr W. Aldren Turner, 18, Harley Street, W.1.

Emeritus Professor E. M. Crookshank, the eminent bacteriologist, died suddenly recently at Ridge Hill Manor, East Grinstead, in his 70th year. His loss will be severely felt, not only in the medical world, but also in veterinary and agricultural science, to which he devoted the later years of his life.

The youngest son of Captain Chichester Crookshank, at an early age he showed a taste for scientific work. He studied under the late Lord Lister, and in 1882, at the age of 24, was selected for special duty in antiseptic surgery on the staff of Sir James Hanbury, principal medical officer of the Egyptian Expedition. He was present at the battle of Tel el Kebir, and received the medal and the Khedive's star for his services. He wrote a report on the antiseptic methods employed at the field and base hospitals of the expedition, and gave valuable evidence before the Royal Commission on the Medical Services in Egypt. In 1886 he was appointed Professor of Bacteriology in King's College, and founded there the first laboratory to be established in England for research and instruction in bacteriology and comparative pathology. He was a skilled hunter of big game, and at his home at East Grinstead were many heads which had fallen to his gun in South Africa and elsewhere.

The Use of Ethyl Petrol

An interim report of the Departmental Committee on ethyl petrol which has been published, supports the conclusion of the United States Government Committee that there are no reasons for prohibiting the use of ethyl petrol.

The investigations made in America are described in the report, and the committee state that, although there is no evidence to show that the use of ethyl petrol as a motor fuel involves more dangers to health than the use of ordinary petrol, they think, for the time being, the precautions indicated in regulations suggested by the United States Committee are desirable. They also point out that adequate ventilation of all garages, whether ethyl petrol is used or not, is a matter of considerable importance, and that the danger from carbon monoxide in an unventilated garage is very serious.

The Glasgow Meeting of the British Association

This year's meeting of the British Association for the Advancement of Science will be held in Glasgow, opening on September 5th. The president, Sir William Bragg, will give an address on "Craftsmanship and Science," reviewing in a wide, rather than technical, manner the relations between science and industry. The two evening discourses will be given by Professor E. A. Westermarck on "The Study of Popular Savings," and by Professor F. G. Donnan, on "The Mystery of Life." Professor Donnan's address will be a study of the present position in biochemical research. Nearly three hundred papers will be presented in the various sections.

Receptions by the Lord Provost and the Corporation will be held in the City Hall, and by the local committee in the Kelvington Art Galleries. Entertainments by public bodies, the Chamber of Commerce, Corporation of Paisley, Royal Faculty of Physician and Surgeons, Platform of the Trades House, Royal Technical College, Institution of Engineers and Shipbuilders, Glasgow and West of Scotland College of Domestic Science, Clyde Navigation Trustees (in connection with their annual inspection of the port and harbour of Glasgow) are also included on the program, in addition to a special service on Sunday, September 9th, in the Cathedral of St Mungo.

NOVA SCOTIA

Dr R M Pearce, Director of Medical Education, Rockefeller Foundation, and Dr D L Edsall, Dean of Medicine, Harvard University, were visitors to Halifax early in August. The particular object of their visit was to make a thorough examination of the equipment and teaching facilities of the medical school of Dalhousie University.

Mr Justice Chisholm has been appointed a member of the Board of Commissioners of the Victoria General Hospital, Halifax, to fill the vacancy caused by the death of Judge Wallace. Mr Justice Chisholm is eminently qualified to serve in this capacity and his appointment has given general satisfaction.

An action for damages to the amount of ten thousand dollars has been brought against the Yarmouth Hospital by a former patient of that institution. The claim is based on the fact that the superintendent of the hospital, a fully qualified nurse, while changing dressings, probed a sinus to the detriment of the patient's condition. The case came up before the July session of the Supreme Court, but only evidence was taken and argument was postponed for a subsequent session of the Court. A number of medical men were called upon for evidence or opinion and considerable difference of opinion was expressed.

Dr E W H Cruikshank has been appointed to succeed Dr Boris Babkin as Professor of Physiology at Dalhousie University. Dr Cruikshank has had a varied experience and is highly recommended, both as a physiologist and a teacher. Dr Cruikshank followed his studies at the University of Aberdeen, King's College, London, and University College, London. At present he has a teaching position at the Medical College, Tatma, India. Dr Babkin is spending the summer in Europe but will return in time to take up his new work at McGill University in the autumn.

Dr G S Eadie, of the Department of Physiology, Dalhousie University, has resigned to accept a position at the Johns Hopkins University.

Dr Mary Stevenson has been appointed assistant to Dr R P Smith, Professor of Pathology at Dalhousie University. She graduated from Glasgow University in 1924. Her technical training was received under Dr Crappell, Western Infirmary, Glasgow.

Dr Clyde W Holland has been appointed to the Chair of Bacteriology, Dalhousie University. Dr Holland graduated at Dalhousie in 1923, his course having been interrupted by overseas service. Since graduation he has had a varied experience and has shown capacity as a teacher.

Dr H L Scammell, of Pictou, has been appointed assistant resident medical officer at the Victoria General Hospital, Halifax.

The trustees of the Payzant Memorial Hospital, Windsor, N.S., have decided to build an addition which will raise its capacity to fifty beds.

Tenders are being asked for a substantial addition to the Ross Hospital, Sydney.

An investigation into the causation of common colds, which is to be carried on over five years and is being financed by the Chemical Foundation of New York, is to be headed by Dr James A Doull, Associate

Professor of Epidemiology, Johns Hopkins University School of Hygiene. Dr Doull is a Nova Scotian and a graduate of Dalhousie.

In order to assure a good representation of Nova Scotia at the Charlottetown meeting of the Canadian Medical Association, it was decided that the annual meeting of the Medical Society of Nova Scotia, which normally would have been held early in July, should be postponed. Inasmuch as this is the year for the seventy-fifth annual meeting of the Society, it was felt that it would be unavailing to cancel the meeting. Arrangements are now being made to combine three events at Halifax in the month of October, when the seventy-fifth meeting of the Medical Society will be held, when the diamond jubilee of the Dalhousie Medical School will be celebrated, and when the Dalhousie Medical Refresher Course will be put on. The Canadian Medical Association is co-operating actively and the program being arranged will undoubtedly attract a very large attendance. Some very special features are being prepared and it is planned that every province of the Dominion will be represented in the "faculty" of the Refresher Course.

The Dental Society of Nova Scotia held its annual meeting at Halifax in July and was largely attended. Several eminent members of the profession from other provinces and from the United States were present and took part in the program. Dr J P Parker, of Sydney, N.S., was elected President, and Dr J Stanley Bagnell, of Halifax, Secretary-Treasurer.

Last winter several cases of typhoid fever developed in the town of Stellarton, and six deaths resulted. Quite recently the husband of a woman who was one of the victims has issued a writ against the town under the Fatal Injuries Act, claiming \$15,000 for damages due to the death of his wife. It is alleged that sufficient care was not taken to prevent infection of the town water supply. The action will be tried at the next session of the Supreme Court. It is rumored that other persons will bring action against the town on the same grounds.

W H HATTIE

Following the Canadian Medical Association meeting in Charlottetown, Dr G Harvey Agnew, of Toronto, the Associate Secretary of the Association, visited most of the hospitals in the Maritime Provinces. From Wolfville to Digby local doctors motored him from place to place, so he visited all the hospitals in the valley. The Hospital Section of the Canadian Medical Association promises to be of considerable value to the smaller institutions.

On the evening of July 14th there was an informal reunion of a number of Dalhousie graduates at a dinner in the Isle Royal Hotel, Sydney, which was followed by a social evening at the Cape Breton Yacht Club.

It is announced that Dr A M Marshall, of Halifax, left early in July for the Hawaiian Islands for several months, to be in charge of a local hospital for that time.

Last month we noted that Dr O W Bliss, of Amherst, was the first patient to be operated upon in the temporary quarters occupied by Highland View Hospital after the fire. He is now spending some time convalescing with his son, Dr Gerald, in Altoona, Pa.

S L WALKER

QUEBEC

The cities of Grand Mère, Outremont, Westmount, Valleyfield, and Kenogami have registered the lowest infant mortality during the month of May, according to the vital statistics issued by the Provincial Bureau of Health. Everywhere throughout the province there is a favourable decrease in general mortality and in infant mortality as compared with the same months of 1926 and 1927. The highest birthrate for the month is shown by the city of Kenogami.

The number of births in May last in the province were 6,768, as compared with 7,305 in 1926, and 7,796 in 1927. Marriages were 1,345 last May, 1,333 in 1926, and 1,467 in 1927. Deaths at all ages, were 3,003 last May, 3,605 in 1926, and 3,359 in 1927. Infant mortality was 872 in 1928, 1,057 in 1926, and 892 in 1927. It is interesting to note that during the month of May no deaths of children under one year of age were reported in Grand Mère, Outremont, Westmount, Valleyfield and Kenogami.

The town of Chicoutimi will be the centre of the sanitary unit for Chicoutimi county, the city council there having unanimously adopted a resolution calling on the Provincial Government to establish one for the county with its headquarters in the city. Chicoutimi is willing to contribute \$600.00 per annum towards the unit, the remainder of the necessary amount

coming for the different parishes, from the Provincial Government, and the Rockefeller Foundation. The city council of Chicoutimi also suggested that the Government be asked to supply the necessary vaccine to prevent any outbreak of diphtheria.

A new chapter dealing with laboratory work has been added to the bulletin issued every two months by the Health Department. This shows that this year, so far this department has made 31 food analyses, 5,262, of milk and cream, 61 examinations for contagious disease, 11, in diphtheria carriers, 42, for drugs, and 6,921 clinical analyses, making a total of 12,328. In milk inspection work, under the new by-law, there have been 9,190 milk tests taken in various restaurants. Eleven convictions were made in the city, while 6,722 inspections were made in the country, with a total of 56,644 cows, 3,932 stables, 3,263 dairies. Arising out of these, 332 notices were sent and 86 dairies banned.

Dr Guillemette, of Baie St Paul, was elected President of the recently reorganized Medical Society of Charlevoix Saguenay. Dr P. E. Paquin was chosen Secretary.

GEORGE HALL

ONTARIO

The annual meeting of the Ontario Medical Association for 1929 will be held on May 28th, 29th, 30th and 31st, in the city of Hamilton. The local committee has already held its first meeting for the discussion of preliminary arrangements.

The annual meetings of the Connsellor Districts of the Ontario Medical Association will be held on the following dates—

- District No 1, at London, on October 26th
- District No 2, at Simcoe, on September 26th
- District No 3, at Owen Sound, on October 10th
- District No 4, at Hamilton, on October 25th
- District No 5, at Barrie, on October 3rd
- District No 6, at Belleville, on September 27th
- District No 7, at Kingston, on October 31st
- District No 8, at Ottawa, on October 24th
- District No 9, at Sarnia, on September 6th, and at Timmins, on October 5th

District No 10 at Port Arthur and Fort William, on September 8th

On July 10th, the Hastings and Prince Edward County Medical Society met at Madoc. An address was given by Dr J. K. McGregor of Hamilton on "Indigestion."

The Renfrew County Medical Society met at Renfrew on July 11th. Dr J. W. Ross, of Toronto, gave a talk on "Abdominal Pain", and Dr Norman

B. Gwyn, of Toronto, spoke on "Pneumonia."

On July 18th, at a meeting of the Northumberland and Durham Medical Society held at Cobourg, Dr H. S. Hutchison, of Toronto, gave a talk on "Goitre."

The Bruce County Medical Society met at Kincardine on July 19th, and was visited by Drs W. P. Tew and J. W. Crane of London. Dr Tew spoke on "The management of certain obstetrical emergencies", and Dr Crane gave a talk on nephritis.

At a meeting of the Huron County Medical Society, held at Wingham on July 25th, Dr A. H. W. Caulfield, of Toronto, gave an address on "Practice and prevention in non-tuberculous pulmonary disease."

On July 25th, the Lambton County Medical Society met at Sarnia, when Dr J. W. Ross gave an address on "Abdominal pain."

Dr C. H. Best, head of the Department of Physiological Hygiene in the School of Hygiene, University of Toronto, has been awarded the Degree of D.Sc. by the University of London for his research in biochemistry and physiology, carried out at the National Institute for Medical Research, Hampstead.

N. B. GWYN

MANITOBA

The infant mortality rate, 59 per 1,000 live births, for the first six months of this year, is the lowest ever recorded for the half year period in the history of Winnipeg.

The tuberculosis survey carried out in Manitoba by the Health and Hospital Committee of the Welfare Supervision Board has been completed and the records have been turned over to M. P. Morrison, actuary of the Monarch Life Assurance Company, for summarizing. After Mr. Morrison's report is prepared for the Minister of Public Health, Hon. Dr. E. W. Montgomery, legislation aiming at the better care of tuberculous patients and protection of non-affected persons will be drafted for introduction at the next session of the legislature.

A highly successful meeting of the Brandon and District Medical Association was held at the Manitoba Sanatorium, Ninette, on August 4th. Short addresses were given by members of the staff, Drs. Ross, Scott, Perrin, Mary McKenzie, Bennett, Morgan, Malcolmson, and D. A. Stewart.

The annual meeting of the Manitoba Medical Association was held on August 10th and 11th. The visiting speakers were Drs. Alexander Primrose, F. F. Tisdall, and R. R. Graham, of Toronto, and Dr. J. C. Meakins, of Montreal.

Dr. W. A. Gardner, of Winnipeg, in company with Dr. Hart of Toronto and Dr. Wright of Montreal, gave

an illustrated address on fractures before a meeting of the Eastern Saskatchewan Medical Association at Broadview on July 11th.

Dr. R. W. Jeffrey, of Monroe, Wash., has located at Carberry, Man.

Dr. A. W. S. Hay is now associated in practice with Drs. N. J. Maclean, P. H. Thorlakson and N. H. Blahie of Winnipeg.

Dr. C. A. Rice and Dr. S. Kobrinsky have been appointed to the honorary attending staff of Grace Hospital, Winnipeg.

ROSS MITCHELL

A mosquito prevention campaign was inaugurated this spring, in Winnipeg and its suburbs, by the Winnipeg Health League, and the Young Men's Board of Trade. A fund was raised by popular subscription for this purpose, which was supplemented by a grant from the City Council. Oiling was carried on extensively, measures were taken to drain low-lying land, and holes where water might collect were filled in. Surprisingly good results were obtained, and it is gratifying to be able to report that the mosquito, which in the past has been the most unpleasant feature of the summer in this neighbourhood, has this year been practically absent. The citizens of Winnipeg and suburbs are indebted to the organizers and workers who have brought this condition about.

ALBERTA

Advertisements have appeared in certain medical journals in Great Britain regarding vacancies in medical practice in western Canada, and physicians interested have been enquiring through the British Medical Association as to the reasons why these vacancies were not filled by Canadians. In such instances it would seem that the advertisers hoped to secure physicians at reduced rates from Great Britain. Since school inspectors receive \$250.00 a month and expenses, Deputy Ministers \$4,500.00 to \$5,500.00 a year and Cabinet Ministers \$8,000.00 and expenses, one wonders why it is that some communities consider that a medical man should accept \$2,500.00 a year and finance his office and the upkeep of his automobile.

Members of the Alberta Medical Association are anticipating an excellent meeting this year on September 18th, 19th and 20th at Edmonton. A splendid aggregate of the professional staffs of Toronto, McGill and Queen's Universities, as well as others, will be present to give lectures, clinics and speak on special subjects, including Professor J. C. Meakins, Montreal; Professor A. Primrose, Toronto; Professor Roscoe Graham, Toronto; Professor J. Millor, Kingston; Dr. F. F. Tisdale, Toronto; Dr. G. H. Agnew, Toronto, and Dr. T. C. Rontlev, General Secretary of the Canadian Medical Association.

The travelling tonsil clinic of the Provincial Department of Health made the rounds of the Peace River District, following out its usual method of procedure. According to reports most of the work was carried out where there were physicians with estab-

lished practices, and not in the outlying places as one would have expected would be the case. Many believe that this bargain counter work with bargain counter attention is destined to be a passing affair. Operations are carried out on a cash basis, hence the needy remain away if short of funds, going later to the family physician where they are sure of service, regardless of time, of distance or of remuneration. If the profession in this province is to learn anything from these clinics, it is that the Government approves of the principle of cash for medical services.

The following physicians have recently registered in Alberta: James Ferguson Brunton, Edmonton; Percy Harry Sprague, Calgary; Ernest Aikman Hunt, Calgary; Torrence James Agnew, Calgary; Gerard Fordyce Chappelle, Edmonton; Herbert Charles Furst, Strathmore; John Joseph Dobey, Gadsby; Lola D. McLatchie, Calgary; Charles Bramwell Rich, Kitscoty; William Barr Murray, Irma; Edward Alfred Johnson, Edmonton; James E. Patterson, Sarnia, Ont.; W. A. MacDonald, Delia; W. E. Ingram, Calgary; J. D. Matheson, Granum.

We are pleased to learn that Dr. R. H. O'Callaghan is making a satisfactory recovery from the operation consequent on his serious accident in July. He expects to leave for England shortly.

Dr. John A. Matheson, a graduate of Toronto University and an interne of the Harper Hospital, Detroit, for the past two years, is now associated with Dr. A. G. Scott, Bassano.

Solution PITUITARY Extract "Frosst"

A STERILE, slightly acidulated, aqueous extract of the posterior lobe of the pituitary gland of cattle, standardized so that each cubic centimeter has the activity upon the isolated uterus of a virgin guinea pig corresponding to 10 International Units [League of Nations' Standard].

- 1—Solution Pituitary Extract "Frosst" conforms to all the requirements of the Canadian Government with respect to potency, hydrogen ion concentration, sterility and quality of glass container
- 2—Solution Pituitary Extract "Frosst" is in addition tested for vaso-pressor activity

- 3—The depressor effect manifested by many commercial samples, and which is due to the presence of non-specific bases (*e g*, histamine) is eliminated by our process of handling
- 4—Freedom from irritation is insured by extremely low protein and inert extractive content

½ c c Ampoules (5 International Units) in boxes of six and boxes of one hundred
1 c c Ampoules (10 International Units) in boxes of six and boxes of one hundred

All operations in the manufacture and standardization of this preparation are conducted in our own laboratories, glands being obtained only from local abattoirs, subject to our supervision

Dr D J M Crawford, of Red Deer, left recently for Toronto, where he has accepted an interne ship in the Sick Children's Hospital

Dr Charlesworth, of Edmonton, a son of the Deputy Minister of Public Works, is rapidly regaining his health, following an operation

Dr Harry Smith, Superintendent of the Royal Alexandra Hospital, Edmonton, has returned to duty, following an operation for appendicitis

Dr J M Hotson, a pioneer physician in the Viking district, is now in practice in Vancouver

Dr Hector McKenzie, formerly of Milo, has returned from British Columbia and is now acting as locum tenens for Dr Meyer of Athabasca

Dr D Wannop, of Nanton, has disposed of his practice to Dr W E Tiffin, of Kimberley, B.C., who formerly practised in Alberta. Dr Wannop will likely return to Southern China, where he had charge of a large hospital prior to the recent revolution

G E LEAFMOUTH

BRITISH COLUMBIA

The sixth annual meeting of the Canadian Society for the Study of Diseases of Children was held in Vancouver on June 29th. When one takes into consideration the very tender age of this society and the far western locale of the meeting, the membership attendance—33 per cent—was indeed excellent. Following as it did on the heels of the midsummer session of the North Pacific Paediatric Society several men from the adjoining States of Washington and Oregon were enabled to remain over for the meeting.

The sessions were held in the Patricia room of the Hotel Georgia, and opened with the presidential address of Dr Geo R Pirie of Toronto. His remarks, and the paper of Dr H P Wright which followed, dealt with an outbreak of acute intestinal infection in Toronto last year. A very prolonged and excellent discussion on the rational approach to disturbances of nutrition in infancy followed. Dr F M Fry's paper, which was read *in absentia* by Dr A P Hart, dealt with the very pertinent question "What is a paediatrist?" and drew attention to the looseness in spelling this and other medical terms. Dr Howard Spohn reported a rare case of "Teratoma of the neck" in a boy of five. Dr Frank H Boone's paper dealt with "Chronic diffuse nephritis in young children with report of a case." Dr H B Cushing of Montreal, outlined the different types of erysipelas antitoxin. The morning session closed with a paper by Dr S G Ross and Jessie B Scriver (by invitation) on the "Use of bananas as a food for normal infants and young children."

The afternoon session opened with the showing of a moving picture reel of a case of "Amniotonia congenita" from the Boston Children's Hospital, discussed by Dr H P Wright. Dr A P Hart's paper on Birkhaug's rheumatic toxin brought out the disappointing results obtained in Toronto with the use of this test, which Dr Birkhaug, said the speaker, appeared to think might be due to a different strain existing in Toronto. Dr Alan Canfield's talk on "Some observations in child life with special attention to feeding and physique" dealt with the treatment of the type of child to which the speaker gave the name "Underling." A case of cerebellar abscess was reported by Dr Geo Bover, in which the apparent impossibility of correct diagnosis had resulted in the death of the patient. Each paper was followed by an excellent discussion. At the business meeting which followed the reading of the scientific papers, the following officers were elected for the coming year: President, Dr Crossan Clark, Secretary, Dr Frank H Boone, both of Hamilton, Ontario (*Bull Vancouver Med Ass*, 1928, xi, 354).

Dr J W Arbuckle, of Vancouver, and Dr J G McKay, of New Westminster, conducted the post graduate tour of Alberta in July, giving lectures and

holding meetings under the auspices of the Canadian Medical, Alberta Medical, and British Columbia Medical Associations. They were accompanied by Drs Geo R Pirie, of Toronto, and S G Ross, of Montreal. Meetings were held at Medicine Hat, Lethbridge, Calgary, Drumheller, Calgary, Red Deer, Stettler, Camrose, Edmonton, and Vermilion. These doctors were accorded an enthusiastic reception and they report very satisfactory meetings.

Another extra mural post graduate tour through out the province will be carried out jointly by the Canadian Medical and British Columbia Medical Associations in August and September. Arrangements have been completed with Dr A T Bazin, Assistant Professor of Surgery, McGill University, Dr A H Gordon, Associate Professor of Medicine, McGill University, and Dr Gordon Bates, of Toronto, to give the lectures and clinics. The itinerary will be as follows: August 27th and 28th, Cranbrook; August 28th, Grand Forks; August 30th and 31st, Kelowna; September 4th, Chilliwack; September 5th, Vancouver; September 6th, Nanaimo; September 7th and 8th, Victoria; September 12th, Prince Rupert; September 14th, Prince George. Dr Theo H Lennie, Vice President of the British Columbia Medical Association, will accompany the speakers from Cranbrook to Vancouver, and Dr H Spohn, of Vancouver, will travel to Prince Rupert and Prince George.

The Vancouver Medical Association had the pleasure of hearing an address by Dr Hilding Berglund, of the University of Minnesota, on his way through Vancouver en route to Peking. Dr Berglund discussed the most recent work in connection with the anemias, particularly the results obtained with the liver diet. At the same meeting Dr Lewis Smith, formerly on the teaching staff of the London Hospital gave an amusing, and at the same time very timely, address on "Mischievous methods in modern medicine."

Dr H A Rawlings, who for the past five years has been in charge of the Rotary Clinic for Diseases of the Chest in Vancouver, is taking up private practice as a radiologist in the city, giving only part of his time to the clinic. Dr W H Hatfield will be associated with Dr Rawlings as part time medical officer of the Rotary Clinic from the middle of August.

Dr H W Hill has been appointed one of the Royal Commission to enquire into the milk situation in the Province of British Columbia. The commission has already held a number of sittings as witnesses. For a number of years the milk supply of the City of

PURE COD LIVER OIL

The highest grade of Medicinal Cod Liver Oil, obtained from strictly fresh livers of Newfoundland Codfish under conditions which produce an Oil of maximum vitamin value

BIOLOGICAL ASSAY

Vitamin A

The biological methods used in assaying for the growth promoting (Vitamin A) value of this oil, follow along the lines adopted by the Department of Pharmacology, University of Toronto, as described in the *Canadian Medical Association Journal*, October, 1924. The standard for "Ayerst" Cod Liver Oil is 400 Vitamin A units per Gm. or better.

Vitamin D

The anti-rachitic (Vitamin D) potency of the oil is determined by observing its value in promoting recalcification in the tibia of animals suffering from experimental rickets. "Ayerst" Cod Liver Oil is standardized to 75 Vitamin D units per Gm. or better.

The photographs of Rat No. 290 on different dates show the reconstructive value of Biologically Standardized Cod Liver Oil.

ANOTHER IMPORTANT FACT!

Ayerst Cod Liver Oil is pleasant to taste. Children take it readily.

In original 4 ounce and 16 ounce bottles only, to assure against loss of potency or impairment of its fine flavour.

Born May 17. On normal diet with mother until June 17. Weight 30 grams.

July 24. After 38 days on a devitaminized diet (from June 17 to July 24). Weight 34 grams.

August 28. After the next 36 days (July 24 to August 28) on same devitaminized diet with the addition of Cod Liver Oil. Weight 70 grams.

UNITED STATES

The American College of Surgeons will hold the eighteenth Clinical Congress in Boston, October 8th to 12th. Headquarters will be at the Statler Hotel and the meetings will be held in the ballroom of the Copley Plaza Hotel and Symphony Hall. The Hospital Standardization Conference will be held in morning and afternoon sessions in the ballroom of the Copley Plaza Hotel Monday, Tuesday, Wednesday, and Thursday

An innovation this year will be the commencement of the clinics in the Boston hospitals on Monday afternoon, continuing through the mornings and afternoons of the following four days. Monday evening's program will include an address of welcome by the local chairman, the address of the retiring President, Dr George David Stewart, New York, the inaugural address of the new President, Dr Franklin H. Martin, Chicago, and the John B. Murphy Oration on surgery by Professor Vittorio Putti of Bologna, Italy. Tuesday, Wednesday and Thursday evenings' sessions will be held in the ballroom of the Copley Plaza Hotel. At the Wednesday evening meeting the visiting surgeons will be the guests of the Boston Surgical Society at a special meeting, when the Bigelow medal is to be awarded. On Friday evening, the Annual Convocation of the College will be held in Symphony Hall when the 1928 class of candidates for Fellowship in the College will be received. The Fellowship Address on this evening will be delivered by Dr William J. Mayo. The annual meeting of the Governors and Fellows will be held Friday afternoon and will be followed by a symposium on Traumatic Surgery, to be participated in by leaders in industry, labour, indemnity organizations, and the medical profession. Ether Day will be celebrated in the Dome Room of the Massachusetts General Hospital on Friday, when a bronze bust of William T. A. Morton will be presented to the hospital. It was in this building that ether was first administered for the production of surgical anaesthesia on October 16, 1846. Several newly completed medical motion pictures, produced under the supervision of the American College of Surgeons and approved by it, will be shown during the Congress.

Reduced fares on the railways of the United States and Canada have been authorized to those holding a convention certificate, so that the total fare for the round trip will be one and one-half the ordinary first class one way fare. Other outstanding features will be the exhibits. In addition to the commercial exhibits the departments of the College will present scientific exhibits. A number of distinguished foreign guests of international reputation have signified their intention of attending. The Chairman of the Boston Committee on Arrangements is Dr Frederic J. Cotton.

Considerable interest has been shown by the medical profession throughout the country in the first "Graduate Fortnight" of the New York Academy of Medicine, on the problem of aging and of old age, which is scheduled for October 1st to 14th, with two sessions daily at the Academy, and clinical demonstrations and lectures of thirty teaching hospitals.

Among the speakers to be present from abroad are Sir Farquhar Buzzard, Regius Professor of Physic at Oxford, and Dr Vittorio Putti, orthopaedic physician of Bologna.

Two sessions daily will be held at the Academy, comprising the following program:

October 1st Afternoon Opening Session Introductory Remarks Dr Samuel W. Lambert, President, New York Academy of Medicine. Dr Louis I. Dublin, Statistician Metropolitan Life Insurance Co. The treatment of arthritis deformans of the hip, Professor Vittorio Putti, Institute Rizzoli, Bologna, Italy.

Evening The doctor—Trainer or healer? Dr George E. Vincent, President, Rockefeller Foundation. Carpenter Lecture Pathological processes in aging. Dr Alfred S. Warthin, Professor of Pathology, University of Michigan.

October 2nd Afternoon. Importance of anatomical pathways in diseases of middle life and old age. Dr Harrison S. Martland, City Hospital, Newark. Postponement in the individual process of aging. Dr Lindsay R. Williams, President, New York Tuberculosis and Health Association. Clinical aspect and management of old age from the practitioner's point of view. Dr Charles F. Collins, New York City.

Evening Syphilis in elderly persons. Dr George M. MacKee, Professor of Dermatology and Syphilology, Post Graduate School. Diseases of the skin in old age. Dr Howard Fox, Professor of Dermatology, New York University.

October 3rd Afternoon Arterial diseases of the brain and cord. Dr Foster Kennedy, Professor of Clinical Neurology, Cornell University. Spinal cord diseases. Dr Edwin G. Zabriskie, Att. Physician, Neurological Institute.

Evening The aging of the heart muscle regarded from a general biological point of view. Dr Alfred E. Cohn, Rockefeller Institute. Dr Alexis Carrel, Rockefeller Institute. Arteriosclerosis and aneurism. Dr E. J. G. Beardsley, Associate Professor of Medicine, Jefferson Medical College, Philadelphia.

October 4th Afternoon Dietetics in old age. Dr Samuel A. Brown, Professor of Pharmacology, New York University. Pharmacology in old age. Dr Alexander Lambert, Visiting Physician, Bellevue Hospital. Alcohol in old age. Dr Samuel W. Lambert, President New York Academy of Medicine.

Newfoundland Fisheries...Source of Mead's Standardized Cod Liver Oil

CONTRARY to the practices of other fisheries, the Newfoundland cod is caught in traps set from only one-half to one mile from shore. Only an hour or so of time, often less, elapses after the fish are caught until they are on the landing stages of the Mead Johnson and Co. rendering plants that dot the coast. 'An hour or less' That means fresh livers only are used in the preparation of Mead's Standardized Cod Liver Oil.

Three thousand miles of rocky shore line on the Newfoundland coast afford ideal feeding grounds for the cod. Numerous indentations and small bays abound with caplin and other small fish, constituting the cod's chief food. It is the abundant food supply along the Newfoundland coast that supplies the high vitamin potency of this particular Cod Liver Oil.

Newfoundland Cod Liver Oil

THUS Newfoundland is particularly well suited for the production of a highly potent cod liver oil. This fact was first established in 1921 and 1922 by the investigations of Mead Johnson and Co. Subsequent researches and comparison with other oils have amply verified these original findings.

Evening Carcinoma of the larynx Dr John E. MacKenzie Senior Surgeon Manhattan Eye Ear and Throat Hospital Diseases of the eye in old age Dr William H. Wilmer Professor Ophthalmology Johns Hopkins University

Programs of special clinics and clinical demonstrations have been arranged in thirty hospitals which are co-operating in the fortnight

The facilities for the study and teaching of medical history at Johns Hopkins University are to be greatly extended. A fund of \$2,000,000 is to be expended on an initial building and its endowment. Part of the scheme is the establishment of the Welch Medical Library and Department of Medical History which is intended to foster historical research and provide a cultural background for the medical profession.

Prof. W. H. Welch is now in Europe collecting medical historical works and other mementoes of interest in connection with the development of the medical profession.

Mr. Edward B. Bobinette of Philadelphia has presented the University of Pennsylvania with a gift of \$250,000 for the establishment of a foundation for the study of the prevention of diseases of the cardiovascular system. It is expected that the fund will eventually reach \$1,000,000. Mr. Bobinette also will present at least \$500,000 to the University fund for the development of education.

It has been announced that Mr. Abram E. Fitch, of New York City, has donated \$1,000,000 to Yale University as a memorial of his son. It is intended for the development of the study of diseases of children and of child life.

Dr. W. M. L. Cohn, formerly Professor of Pathology at Jefferson Medical College and author of an outstanding textbook on his subject, died at Atlantic City on May 20th in his sixty-fourth year.

A graduate of Jefferson in 1880, he became professor of pathology in that institution in 1896. In 1892 was appointed pathologist to the Philadelphia Hospital, a position that he held till his death and was also President of the Faculty. During the World War he served as a colonel in charge of Base Hospital 38 in France.

Dr. Cohn wrote much on pathology, bacteriology and sanitation and had an international reputation for his work in preventive medicine.

GENERAL

Second International Congress of Radiology

This year Stockholm entertained the radiologists of the world at the Second International Congress.

Our welcome to Sweden cannot be too heartily stressed, as not only the City of Stockholm but the whole Kingdom of Sweden lavished hospitality on the delegates. The Crown Prince officially opened the Congress in the stately concert hall of Stockholm and subsequently was an attentive and interested listener on several occasions.

Eight hundred delegates were present, many of whom were accompanied by their families. Noticeable were physicians from as far away as Japan,

China and Australia. The United States and Canada were represented by large delegations. The Canadians present were Drs. W. A. Bauld, Montreal, Gordon, Montreal, C. M. Henry, Regina, A. S. Kirkland, Saint John, McNeill, London, H. MacIntosh, Vancouver, Malcolmson, Edmonton, A. Pirie, Montreal, Proulx, Vancouver, Quint, Calgary.

The first noteworthy feature was the exactness and perfection of the details of the preliminary organization, largely due to the ability and industry of Dr. Axel Renander and his associates. Every visitor to Stockholm will carry away the memory of his experience there as an example of perfect arrangement.

Weston's DIGESTIVE

A "whole meal" biscuit endorsed by doctors and dietists

Weston's DIGESTIVE is a real "health biscuit" made from the original old English recipe of the largest selling health biscuit in the world.

It contains, in delicious palatable form, mild laxative qualities especially suited to convalescents. Weston's DIGESTIVE is the only "fancy biscuit" many dyspeptics can eat.

George Weston Limited, Toronto
Makers of "Biscuits as they are made in England"

The basis of such perfection was laid three years ago, and the work will be finished this fall in the publication of papers and reports in *Acta Radiologica*.

Entertainment was more lavish than could reasonably have been expected. The King and Queen of Sweden held an afternoon reception for the delegates and their ladies at the Royal Palace. The official delegates were dined by the Corporation of Stockholm in the Town Hall which, by the way, is one of the most magnificent examples of Scandinavian architecture. Many private homes were opened for more personal entertainment. The social side of the Congress was concluded by a dinner and dance at which about twelve hundred people were guests.

The scientific papers will be reported in current x-ray papers and in the various allied publications. It will, therefore, suffice here to say that most valuable contributions to the science of radiology were provided by many speakers from many lands. The official languages were French, German and English.

The exhibition of new equipment was extensive and was housed in the Stockholm Art Gallery. The apparatus included much that was novel, and inspiring impressions were received on how much there was being done by the physicist and engineer in aid of our efforts at diagnosis and therapy. The perfection of the Philips and Møller x-ray tube was of interest to all.

Simultaneously with the meetings of the general congress a series of committee meetings were convened dealing with first, the standard of x-ray protection, second, standards of protection for radium workers, and, third, the adoption of a standard of x-ray dosage. The British committee reported a series of proposals for protection from x-ray and radium emanation which were adopted. The Swedish committee collaborated on the several safeguards for radium workers and their report was also officially adopted. The suggested standardization of x-ray dosage was accepted. The details will be published later.

As Canadians, we returned home satisfied that much of our work is being well done and determined that in other departments improvements are necessary and that new methods will be given a fair trial.

At the Congress it was announced that the King of Sweden had received, on the occasion of his seventieth birthday, a gift of five million Swedish Crowns, as a token from the Swedish public, of their esteem and love for their Sovereign. The King graciously passed this rich gift to the Radium Institute, the Radium Hemmet, to be used for the further investigation and possible cure of cancer.

The rest of the world owes much of the knowledge of radium to the Swedish therapists under the inspired leadership of Dr. Gustaf Forsell, who was the President of the Convention just closed.

A. STANLEY KIRKLAND

A Gala Day at the Severance Union Medical College, Seoul, Korea

It is not given to many men to see statues of themselves erected during their lifetime. Within the last few weeks this good fortune has come to Marshall Foch. Now we hear of another instance, this time in the case of a man devoted to the arts of peace, Dr. O. R. Avison, President of the Severance Union Medical College.

Dr. Avison was born in Yorkshire, England, sixty-eight years ago. Coming to Canada early in life, he received his education at the high school, Almonte, later taking a teacher's certificate. He graduated from the Ontario School of Pharmacy in 1884 and from the Toronto School of Medicine in 1887. For a time he was on the teaching staff of the Medical Faculty of Toronto University, as well as that of the

College of Pharmacy. During the same period he built up a large practice. All this he gave up to become a medical missionary in Korea. In August, 1893, he arrived in Seoul, and took charge of the Royal Korean Hospital, which had been established by the Emperor, and was also appointed physician to the Imperial family.

Returning to America in 1899 he spoke at a Mission Conference in New York on the necessity of establishing a medical school in Korea for the training of native medical men. A man sitting in the balcony of the hall seemed to be paying close attention to what was being said. At the close of the meeting he came to Dr. Avison and asked him if he had his plans for the medical school. Dr. Avison replied that he had. "Then," said the man, "go ahead with them." He was Louis H. Severance. With a gift of \$25,000 from Mr. Severance the first hospital building was erected in 1904. In 1909 Mr. Severance donated a further gift of \$35,000, to provide a building for the medical school.

In 1917 the medical college was recognized by the government, and in 1923 was further accepted as fully qualified to graduate students in medicine who might practice without other examination by the government.

As the result of another campaign in America in 1924 Dr. Avison was enabled to secure funds for a new hospital, which was erected this year.

Dr. Avison has received many honours at the hands of the Koreans, as well as honorary degrees from Toronto University (M.D.) and Wooster, Ohio (LL.D.).

The twentieth of March, 1928, was signalized in Seoul by a triple event, the unveiling of a statue to Dr. Avison, President of the Severance Union Medical College, the graduation of doctors and nurses from the Medical School, and the opening of the new wing of the hospital. The Severance Compound presented an animated scene when hundreds of relatives and friends of the students and the school came from far and near to attend the exercises.

Dr. S. H. Hong, President of the Alumni, presided at the unveiling ceremony and made a very appreciative speech, in English and Korean. The statue bears the following inscription in English, as well as one in Chinese—

"O. R. Avison, Pharm. G., M.D., C.M., (University of Toronto, Hon. Causa), LL.D. Born in England, educated in Canada, Medical Missionary to Korea since 1893 (under the Board of Foreign Missions, Presbyterian Church in U.S.A., but the Servant of all the Missions of the Christian Church), President of Severance Union Medical College, Seoul, Korea. Dr. Avison's Students, the Alumni of Severance Union Medical College, have erected this statue as an expression of their appreciation of his love, of their gratitude for his great work for Korea and of their intention to continue the same kind of service to their people in the Name and Spirit of the Lord Jesus Christ, 1927."

A congratulatory address was delivered by Baron Yun Tchi Ho, which was a gem of humour, pathos, and brevity. It ran as follows—

"Dr. Hong asks me to make a long English speech and then to translate it into Korean—and all this in three minutes. If I could accomplish all that, as Dr. Hong desires, I should deserve a statue myself."

"Dr. O. R. Avison has done three wonderful things during the thirty-five years past. When he took charge of the Korean Government Hospital, he found in it one patient and forty 'chuses' or officials. We can easily see what a time he must have had in dealing with such a situation. He would probably have found it easier to handle forty patients and one chuse. Out of that unpromising beginning he has literally created this splendid Severance Hospital that we see to day."

VACCINATION AGAINST DIPHTHERIA

For the five-year period 1920-25 in the Province of Ontario, *one death in every six* among children between 2 and 14 years old was due to diphtheria

The majority of deaths from diphtheria occur during the months of the school year.

Diphtheria may be prevented by the use of Diphtheria Toxoid (Anatoxine-Ramon)

Diphtheria Toxoid as developed by Ramon of the Pasteur Institute, Paris, results from the incubation of diphtheria toxin with formaldehyde. It is a particularly stable, accurately standardized antigen which is *absolutely non-toxic*. It contains no serum and is therefore incapable of inducing sensitization to anti-toxins or sera

In the past three years, diphtheria toxoid has been administered to approximately 500,000 individuals in the Dominion of Canada. Three subcutaneous doses, with an interval of three weeks between doses, have been found to give highly satisfactory results

Diphtheria Toxoid (Anatoxine-Ramon) is available in 1-person, 6-person and 12-person packages. Information regarding its use will gladly be supplied upon request

CONNAUGHT LABORATORIES

Canada

"He started a medical school without text books, and, worse still, without a vocabulary to convey his ideas. Yet in spite of all these difficulties and discouraging circumstances he has created a medical school which is a prince of its kind, not only in Korea but in all the Far East."

"The third wonderful thing he has done is this, anyone who has accomplished such great tasks may well become famous as Dr. Avison is to day, but the wonder is how he could have managed to become famous and fat at the same time."

"It was very thoughtful on the part of the Alumni Association of the Severance Medical College to express their appreciation and gratitude in the form of a statue for the man whom they love and honour. Some think it is not quite orthodox to erect a statue for a man while he is living. But orthodox or heterodox, I think it more rational to strow some flowers on the paths which a man walks on than to heap floral crowns on his coffin."

"There is one thing I wish the Alumni Association had found feasible to do, that is to have erected another statue by the side of the doctor's for Mrs. O. R. Avison. I suppose they thought it unnecessary since the fact that she has made it possible for the doctor to do his great life work so well, and the fact that she has given two missionary sons to Korea are sufficient memorials for her, better than can be expressed in bronze or marble. I thank you, Dr. and Mrs. Avison, in the name of the Korean people, for the great service you have done for us."

Immediately after this ceremony graduation exercises took place, eight receiving degrees in medicine and three diplomas in nursing. The graduates of the school, since its inception, number 175 in medicine and 77 in nursing.

The new hospital wing, the gift of Mr. J. L. Severance, Mrs. F. P. Prentice, and a few other donors, was then dedicated, and formally opened by Mrs. O. R. Avison.

The gifts of the Severance family to this remarkable college and hospital have amounted to 500,000 yen, in addition to which they contribute about 47,000 yen annually to the budget of the institution.

Courses at Paris

The following is the program of the post graduate courses in medicine that are to be given in English in Paris next autumn, under the auspices of the Dean and the Faculty of Medicine of the University.

PROPEDEUTIC MEDICAL CLINIC

October 29th to November 3rd, inclusive.
In the morning practical demonstrations will be given at the bedside, under the guidance of Professor Emile Sergent. The afternoon will be devoted to theoretical instruction.
Dr. F. Bordet, Lipiodol in the diagnosis of diseases of the respiratory tract.
Dr. Oury, Bronchial forms of pulmonary tuberculosis.
Dr. Turpin, Carcinoma of the bronchi.
Dr. Kourilsky, Lung abscesses.
Dr. Benda, Bronchial forms of pulmonary syphilis.
Fee 500 francs.

CARDIOLOGY

October 20th to 30th inclusive.
Prof. Antonin Clere, Coronary obliteration in pathology, Practical demonstrations (clinical, anatomical, electrocardiographic, etc.), The cardiac complications of pregnancy, Pathological ventricular rhythms, Syndromes referable to the pulmonary artery, Ouabain in cardiac therapeutics.
Fee 500 francs.

PÆDIATRICS

October 8th to 20th, inclusive.
Dr. Weil Halle, The healthy child. Puericulture and its organization in France, Operation of the School of Puericulture, Feeding of infants, Diet kitchen, practical work, Infantile hypotrophy, Thymus hypertrophy, Vaccination against diphtheria, The so called acetonaemic vomiting, Bases of vaccination against tuberculosis, Practice of anti tuberculosis vaccination with BCG.

Dr. Armand Delille, Organization of children's hospitals in Paris, Acute adenoiditis and otitis in infants, Bronchopneumonia, Pulmonary gangrene, Bionchectasis, Intratracheal injections of lipiodol, and radiological examinations, Measles and its complications, Early stage of tuberculosis in children, Bacteriological diagnosis of tuberculosis in children, Artificial pneumonia in children, Local tuberculosis in children, with the value of heliotherapy and actinotherapy, Types of anemia in infants.
Dr. Piorret, Hydromineral treatment of lymphatic statos in children.

Fee 1,000 francs SURGERY OF THE DIGESTIVE TRACT AND LIVER

October 15th to 20th.
Professor Antonia Gosset, Duodenal ulcer, Carcinoma of the pylorus, Appendicitis and its complications, Cholecystitis, Gall stone in the common duct, Surgery of the colon, Clinic with radiographic section and pathological specimens.
Professor Gosset will also conduct operations and give technical demonstrations on surgical procedure at the Supérieure.

In the afternoons, at the "Ecole pratique de la Faculte de Medicine," a course in operative surgery will be conducted on the cadaver, under the direction of Dr. Marcel Thalhheimer. Each attendant will perform the operations demonstrated the same morning with the technique of Professor Gosset. Lessons on the anesthetized dog may take place in the Laboratory of Experimental Surgery, provided the attendance is sufficiently large.

Fee 500 francs THE SURGERY OF THE EYE

Drs. Morax, Magitot, Bolack, and Hartmann.
Ten lessons on this subject will be given, beginning on October 2nd, with exercises on the human cadaver and pig's eyes. Each attendant will perform the operations. Only a limited number can be accepted. These lessons will be given every other day, lessons in Otorhinolaryngology will be given on the intervening days.

Fee 500 francs THE SURGERY OF THE EAR, NOSE, AND THROAT

Professor F. Lemaitre, Drs. Aubin, Maduro, and Remy Neris.
These lessons will begin on October 3rd, and each attendant will have opportunity to perform operations on the human cadaver and on the dog.
Only a limited number of pupils can be accepted.

A certificate, signed by the Professor and the Dean of the Faculty of Medicine of Paris, will be given after each course to every doctor who has attended it regularly.

The King of Sweden's Birthday Present

It is estimated that the King of Sweden's seventieth Birthday Gift Fund, which, by his Majesty's wish, is to be applied to cancer treatment and research, already amounts to £300,000. An interesting contribution to the fund was the £300 received from the Quillavote tribe of North American Indians, of which Prince William of Sweden, Duke of Sudermann, was made a chief, with the title of "Lono Eagle," during his recent lecture tour in the United States.

Book Reviews

Creatine and Creatinine Andrew Hunter, M.A., M.B., F.R.S.C., Professor of Biochemistry in the University of Toronto 281 pp 14 shillings Longmans, Green & Co., Ltd., London, New York, Toronto, Calcutta, Bombay, and Madras, 1928

Biochemistry, although the most recent division of science, is already amongst those possessing a most prolific literature. It is impossible for any biochemist, let alone others interested in biochemistry, to read the whole of the literature of the subject. Monographs dealing authoritatively with different phases are therefore obviously a necessity. The series of monographs edited by Dr Plimmer and Sir F. G. Hopkins is the earliest and most complete of such attempts to cover the subject, and the present volume is a valuable addition to it.

Creatine and creatinine, the one a constant and important constituent of muscle, the other a constant and important constituent of urine, have long provided puzzles to biochemist and physiologist, both as to the source of creatine, and its function whereby creatinine is formed as an excretory product. These puzzles have in large part still to be solved, although the recent discovery that creatinine exists in muscle mainly as a creatine phosphoric acid of peculiar constitution, whose dissociation and recombination are intimately connected with muscle function, suggests that more complete solutions of the puzzles will shortly be forthcoming. Although this work is so recent that only a brief mention of it in an addendum was possible in Dr Hunter's book, yet anyone wishing to appreciate its significance properly, and to watch with understanding the unravelling of these important problems, will find the work a necessity.

The book consists of nine chapters, four devoted to an accurate statement of the known chemical facts and the biological distribution of creatine and creatinine, and the remainder to a cautious and critical but fair survey of the facts concerning the metabolism of these compounds, and the various theories that have been put forward concerning this metabolism and their function. A complete bibliography is appended.

The book is of course an essential addition to the library of the biochemist. Others interested in biochemical problems will find in it a clearly written and interesting account of an important phase of the chemical processes of the living organism.

A. T. CAMERON

Atlas of Human Anatomy Dr Johannes Sobotta Edited from the Sixth German edition by J. Playfair McMurrich. Vols I, II, and III. Profusely illustrated. Price for set of three volumes, \$15.00 G. E. Stechert & Co., New York, 1928.

An atlas of human anatomy should aim at supplying a great number of clear original illustrations which can be used for revision work by the student of anatomy and for reference work by the practising surgeon. These two points of view are not coincident. The student requires accurate pictures approximating at times to almost diagrammatic representation of a dissection which will be an accurate guide to him in his operative work, in other words a life like picture. To adhere rigidly to one ideal would depreciate the value of the book for the other class of worker. The artist who executed the illustrations has succeeded in steering skillfully between

the blackboard diagram on one hand and a photographic print on the other. The text which accompanied the original English edition has been pruned, leaving but a reasonable amount of descriptive matter to explain the plates.

It is refreshing to see that the editor has adhered to the B.N.A. as the nomenclature for the book. While one must admit that in places the terminology is cumbersome, there can be no doubt that it has made possible the accurate interpretation of anatomical descriptions in other languages. It seems a great pity that this rational and international nomenclature has not been adopted by many clinical teachers in this and in other countries. Whether this is due to the inertia of age or the conservatism which often ensues after years of didactic teaching, it would be vain to speculate.

J. BEATTIE

Manual of the Practice of Medicine A. A. Stevens, A.M., M.D. 12th edition 657 pages Price \$3.50 London and Philadelphia, W. B. Saunders Co., Toronto, McAlinsh & Co., 1928.

Any publication of this nature which has reached the twelfth edition must meet the hearty approval of a large number of medical readers. It is prepared especially for students but is also a handy book of reference for the general practitioner, being relatively brief but inclusive in its treatment of medical conditions.

There is a chapter at the end of the book dealing briefly with skin diseases, as well as a preceding section on diseases of the nervous system.

C. E. BROWN

Ophthalmoscopy, Retinoscopy and Refraction W. A. Fisher, M.D., F.A.C.S. Second edition revised. 291 pages, 260 illustrations. Price \$4.25 F. A. Davis Co., Philadelphia, 1927.

The author has made a sincere and painstaking attempt to condense into a short book, for the benefit of the student and the general practitioner, the three difficult subjects of ophthalmoscopy, retinoscopy and refraction.

The first half of the book deals with the various ocular diseases and their recognition by means of the ophthalmoscope. With the help of an ingenious invention of the author's, a tubular piece of wood representing the eye, and by the use of coloured pictures, the student is enabled, with the ophthalmoscope, to become familiar with the diseases of the fundus. There are some excellent coloured plates of the fundus lesions of the fundus to be studied, and the notes to each plate are short and to the point. The author's method of writing in short paragraphs with headings in heavy type is effective for his purpose of teaching.

There is a chapter on the Field of Vision which every medical man would do well to familiarize himself with, and a helpful chapter on the systematic examination of the eye.

When one comes to the latter half of the book dealing with retinoscopy and refraction the reviewer confesses to a feeling of misgiving. The author begins by insisting that "The fitting of glasses," or in other words retinoscopy and refractions, is easy and belongs to the general practitioner. Whether one agrees with this view or disagrees, a very fair attempt is made to simplify and teach the exceedingly difficult and technical subject of refraction. Optical principles

Helping the Doctor to "Appear Well"

Even where his practice is small and his income inadequate a doctor must "appear well"

His profession gives him social eminence, but it thereby involves unusual financial demands

And that condition persists throughout life He must "appear well" to establish and maintain his position at the beginning of his career

He and his family must continue to "appear well" when, his practice having become large and established, he otherwise could save a good portion of his larger income

And he must "appear well" in late life, when he can no longer follow his profession, because that is the manner of living to which he has become accustomed

At every stage, the need of some adequate form of protection in case he should become incapacitated or die, is one of the most disturbing problems which doctors face

The Sun Life Company has a plan that solves the problem and disposes of the worry Let us diagnose your case

Sun Life Assurance Company of

HEAD OFFICE

are considered, the different kinds of lenses and their use described, with many pages of diagrams of the refractive errors, *viz*, myopia, hyperopia, astigmatism, and presbyopia. The objective use of the retinoscope is described and finally the subjective test by means of the trial case of lenses, even to the fitting of the spectacles themselves.

Besides many coloured plates, the book is well illustrated with drawings and photographs. There might be less confusion to the student were the charts of the visual fields in chapter VI uniform, *i.e.*, all outlined in black.

There are some statements made that are obviously out of date, such as "The use of cylinders in retinoscopy for the estimation of astigmatism is unnecessary." Professor Lindner of Vienna has shown that, on the contrary, the use of cylinders in this connection is of the utmost value. And again "Cycloplegics are rarely if ever, required in patients over forty years of age and never in those over fifty."

There is an interesting chapter by Dr. Von Der Heydt on the examination by red free light, the Gullstrand binocular ophthalmoscope, and the use of the slit lamp.

One can easily catch the enthusiasm of the author in his endeavour to equip the general practitioner with a valuable means of diagnosis of disease, *viz*, the ophthalmoscope, but one cannot without difficulty go so far as to advise him (the busy practitioner) to add as well the tonometer, the perimeter, the retinoscope and the trial frame.

S. O. McMurtry

Transactions of the American Surgical Association
Vol. XL Edited by John H. Jopson, M.D.
William J. Doran Co., Philadelphia, 1927

Like many of its predecessors, this volume of the "Transactions" presents the opinions of some of the most prominent surgeons of the present day on a wide variety of surgical conditions. Of the many sections of interest two deserve special mention—anaesthetics and thoracic surgery. The papers on these two subjects and, equally important, their discussion, gives the reader a fairly well balanced digest of present day surgical opinion.

L. H. McKim

Health and Wealth, A Survey of the Economics of World Health Louis I. Dublin, Ph.D., 1928,

Harper and Brothers, New York and London, 361 pp with index

This book represents a compilation of addresses and articles prepared by Dr. Dublin during the past five years. They are statistical in character but have been written in the popular style and for the lay mind. There are therefore, no references to coefficients of correlation, to probable errors, or to other statistical mysteries. For the physician there is a fund of useful information which is easily understood for it must be remembered that from the standpoint of the statistician the physician is as much a layman as anyone.

Through all the fifteen chapters runs the theme of the prevention of disease. The great cost of disease is discussed and compared with the comparative cheapness of its prevention. From the great wealth of statistical data to which the author has access, material has been selected for strong essays on important social and public health problems of the day. The chapters on infant and child hygiene, on tuberculosis, and on the mortality of the negroes are very optimistic in tone, those on heart disease and cancer less so. The essay on birth control must have caused a disturbance in the ranks of the neo-Malthusians when it was first read at the Sixth International Neo-Malthusian and Birth Control Congress. Dr. Dublin apparently thinks that much of the propaganda for birth control is pernicious and does not hesitate to say so.

The chapter on prohibition gives small comfort to the protagonist of the Volstead Act. It is true that vital statistics have shown a striking reduction in

mortality following the passage of the 18th Amendment, but this could as well be attributed to the influenza epidemics as to decrease in alcohol consumption. One would expect that the improvement in mortality, if due to prohibition, would become cumulative. It should not show its fullest effect at the beginning. The crude death rate of the United States Registration States of 1900 shows the most favourable year from the standpoint of mortality to be 1921, the year following the establishment of prohibition. Since that year the death rate has been rising slightly. When the crude death rate is dissected and specific rates according to age and sex are given, it is shown that the death rates of middle aged and old males have been increasing very definitely since the low year, 1921. It is pointed out that the death rate from alcoholism has been constantly rising in the United States since the marked fall of early prohibition years. Deaths from alcoholism are now almost as frequent as they were ten years before the prohibition era. It is comforting to Canadian readers to know that the death rate from alcoholism in Canada, according to the experience of the Metropolitan Life Insurance Company, is only about a quarter of that in the United States.

In the final chapter, the author estimates a reasonable life extension goal. Instead of the present expectancy of life at birth in the United States of approximately 58 years, he believes that a life expectancy of nearly 65 years is possible. Nor is this extension calculated solely on a saving of young lives. Dr. Dublin thinks that it is quite reasonable to expect an improvement in the life expectancy of old people. This improvement, it may be stated, does not appear to be taking place at the present time, but with the development of the practice of periodical examination it can be confidently hoped for.

Is there a real toxemia in intestinal stasis?

Two views on the relation of constipation to health

THE classic view of constipation ascribes the evils of intestinal stasis to the absorption of putrefactive products into the blood. Known as the "chemical" explanation, this view is still the accepted one among the majority of the medical profession.

An opposing view is, however, being energetically promoted. Conveniently described as the "mechanical" theory of constipation, this modern view holds that there is no true toxemia in intestinal stasis. In the words of its most enthusiastic proponent, "The effects (of bowel stoppage) follow so closely on the appearance and disappearance of the stimulus that they must be produced directly through the nervous system."

Will this modern view displace the older explanation? The physician who has followed both sides of the controversy is apt to find the question a puzzling one. But authorities do not disagree on one point: that whatever the reason *why* constipation is dangerous, it still *is* dangerous, that now, as ever, it is of vital concern to keep the intestinal tract *clean*.

It is because of its anti-putre-

factive power and its ability to stimulate—gently and naturally—the peristaltic action of the intestinal muscles that fresh yeast is today being prescribed by greater and greater numbers of physicians both in this country and abroad.

Fresh yeast increases the bulk and moisture of the fecal masses. Unlike cathartics, it does not form a habit. Nor does the ingestion of large quantities produce the slightest harmful result. As many as fifteen cakes daily have been ingested experimentally.

PHYSICIANS usually suggest three cakes of fresh yeast daily, one before each meal, or between meals. It may be eaten just plain, or in water—or any other way the patient prefers. For stubborn constipation physicians have found it most effective when suspended in a glass of hot (not scalding) water, before each meal and at bedtime.

A copy of the latest brochure on yeast therapy, containing a bibliography of articles on the subject, will gladly be mailed on your request. The Fleischmann Company, Dept. 472, 208 Simcoe St., Toronto, Ont.

A Correct Shoe Is Often Indicated

A physician in charge of the clinic of a prominent eastern university, specializing in disorders of the abdomen, says that he examines the feet of every patient who comes under his observation. He believes that the maintenance of foot health and correct posture will do much to prevent those troubles which have become his specialty.

Being a wearer of the Cantilever Shoe, and knowing its advantages, he recommends it to his patients as an aid to quicker recovery.

As the teeth often affect general health, so misalignments in the foot structure can cause stomach disorders, fatigue, nervous exhaustion, pains in the leg, thigh and back, many rheumatic symptoms, etc.

The wearing of well shaped flexible shoes which give corrective support and exercise will restore the feet to normal alignment and strength. This is the important mission of the

Cantilever Shoe

(For Women, Men and Children)

In the Cantilever Shoe, the requirements of a correct shoe are combined in the exact proportions, namely —

- 1 Lasts shaped along normal anatomic lines
- 2 A straight inner border which follows the form of the normal foot
- 3 Room for all the toes without crowding
- 4 Heels of moderate height and balanced to distribute the weight correctly while standing or walking
- 5 Flexible shanks (arches) which support the foot arches, but also allow freedom of action to the arch muscles, that they may strengthen through exercise

Cantilever Shoes being fashioned in the approved mode, patients take pride in wearing them and gain the healthful benefits without any conspicuous or conscious effort.

Atophan

(Trade Mark)

THE ORIGINAL PRODUCT
A Standard Remedy in Rheumatism and Gout.

Extract from a recent (1926) Text Book of Medicine

" It (Phenylquinolin (Atophan)) is most useful in averting attacks. It is given in tablet form gr $\frac{1}{2}$ three times a day for three days of each week. It increases the output of uric acid in the urine and decreases the amount of uric acid in the blood. *It may be given in this way every week without causing any ill-effects*, and should prevent the continued accumulation of uric acid in the body. The patient should continue to take it in a reduced dosage for the rest of his life."

ANTIPLLOGISTIC—ANTIPYRETIC—ANALGESIC

Tablets gr $7\frac{1}{2}$ —Tubes of 20—Bottles of 100 and 250

Dragees gr $1\frac{1}{2}$ (Keratin coated) Bottles of 100

DOSE—Two tablets thrice daily in water followed by a glass of—preferably—alkaline water

'Atophan' Balsam, which is absorbed by the skin with extraordinary rapidity, admirably supplements 'Atophan' internally

Atophanyl

(Trade Mark)

For Parenteral Administration

An Association of 'Atophan', Sodium and Sodium Salicylate in which the properties of its components are mutually supplemented and enhanced

Intramuscular and Intravenous Injection

Cartons of 5 ampoules of 5 cc for Intramuscular Injection
Cartons of 5 ampoules of 10 cc for Intravenous Injection

Medinal

(Trade Mark)

The Safe Soluble Hypnotic

Induces a restful refreshing sleep which resembles the natural, without unpleasant sequelæ or a cumulative toxic effect

Rapid Absorption and Elimination

Original Packages, Tablets (gr 5 and $7\frac{1}{2}$), Tubes of 10 Bottles of 100 and 250
Dose One—two tablets as required

Who Would Trade in a Snook?

An extract from a report by a Victor representative, following his call on one of the largest clinic in the country

"I just returned from ——— clinic and find the Snook Transformer that was installed in 1924 grinding out as strongly as ever. On Tuesday they ran two hundred chests, which called for four hundred exposures

"I want to call your special attention to their 100 M A Coolidge Tube which they have been using on their Snook machine not quite a month. Radiographs of 3695 patients, or a total of 7308 exposures, were made with this tube and it is still going strong"

To give such consistent service a machine must be correct in design.

A FEW months ago a Victor representative called on a physician who for several years had been using a Snook machine in his completely equipped X-ray laboratory

This physician, being successful both professionally and financially, had come to the conclusion that inasmuch as he turns in his auto every other year or so, to get the advantages of the latest model, it was high time that he turned in his Snook for the same reason. The idea was soon dispelled, however, when the doctor was informed that even though he had purchased his Snook ten years ago, it would be equal to all demands of present-day technic in radiographic diagnosis

The Snook stands alone in this respect, and users in all parts of the world attest to the economy of their original purchase, also to the advantages in having a machine with which they can produce radiographic results second to none, and continue to do so consistently

There is only one SNOOK!

Would it look like a fever chart?

IF YOU plotted the performance of the X-ray intensifying screens in your various cassettes would it give you a healthy record or would it look like a patient's fever chart? There should be no variation your chart should be a straight line. Lack of uniformity in screens means interference with control of the known variables such as time of exposure milliamperage spark gap positioning of the patient, etc.

The possibility of any difference in screens can be eliminated by selecting PATTERSONS. Absolutely UNIFORM in performance, they permit the radiographer to use cassette after cassette without giving a thought to the screens. Possessing SPEED LACK OF GRAIN FREEDOM FROM LAG and CLEANABILITY.

Pattersons are strong and pliable in construction and practically impervious to dirt. These features, assuring consistent, satisfactory results, make them the choice of leading roentgenologists everywhere.

We shall be pleased to send a sample screen free of cost for the radiographer's own test.

McKesson Universal Unit No. 100

The McKesson Gas-Oxygen Machine

is not limited to the amount of pressure it can deliver to the patient

The McKesson machine not only regulates the pressure of mixed gases delivered to the patient, but in addition, it maintains that pressure and mixture, and furthermore stops the flow of gases when that pressure is secured, thus preventing any escape or waste of gas due to the accumulation of too much pressure

The McKesson machine is most simply controlled, since one screw, namely the pressure screw, regulates the pressure at which the gases are delivered into the inhaler, and only safe pressures may be administered

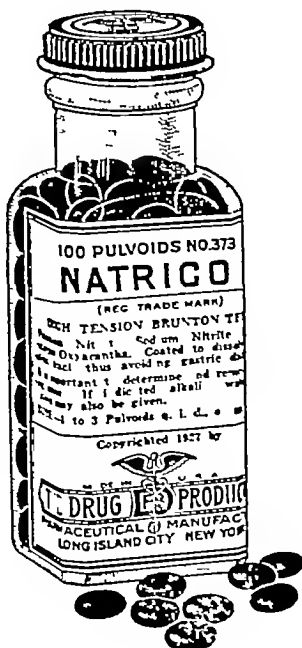

Other unique features are the emergency valve for artificial respiration, the automatic valves, which regulate the intermittent flow of the gases, and the re-breathing attachment which prevents the elimination of too much carbon dioxide from the blood

A New EPHEDRINE NASAL SPRAY

for promoting

Sinus Ventilation and Drainage

EPHEDRINE INHALANT, Swan-Myers contains 1% solution of Ephedrine alkaloid in light mineral oil, colored for identification and fragrantly perfumed with oil of rose

It contains no aromatics, such as menthol, thymol, camphor or eucalyptus which frequently irritate and sting. Patients experience no discomfort from the cold air after the use of this spray. Applied as an oil spray, or as drops in the nose, this Inhalant will contract capillaries, reducing swelling of the turbinates and diminish hyperemia. It promotes sinus ventilation and drainage. Its action is prompt and sustained.

DRYCO
for Infant Feeding*

1. Years of international clinical history have established its merit.
2. Current medical literature bears frequent reference to its efficacy.
3. Thousands of physicians know from experience that it can be depended upon for good results.

There is as great a difference between Dryco and ordinary dried milks as there is between certified and other liquid milk. The results obtained with the use of Dryco have made it an incontrovertible fact that Dryco is ideal for infants deprived of breast milk and is of especial value in difficult feeding cases.

Occult Constipation

Occult constipation (from an X Ray) 24 hours after opaque barium meal. There has been one small stool as usual. Note the deep haustrations and partial dilatation of cecum.

THE menace of occult constipation lies in the fact that the patient may have regular daily evacuations, and is therefore unaware of

the constant retention of fecal matter, which may ultimately form a hard and deep coating on the intestinal wall, leaving but a small passage through which painful and partial evacuation takes place.

When headaches, lassitude, and the conditions usually associated with the development of intestinal toxemia lead to the suspicion of hidden constipation, the reliance of many physicians is on AGAROL, the original mineral oil and agar-agar emulsion. Combining lubrication with softening of the fecal mass and gentle peristaltic stimulation, AGAROL is particularly indicated in cases of occult constipation—because of its positive, yet gentle action, without habit formation.

A generous trial quantity sent on request

WILLIAM R. WARNER & CO., LTD

Manufacturing Pharmacutists since 1856

TORONTO, ONT.

AGAROL is the original Mineral Oil—Agar Agar Emulsion and has these special advantages:

Perfectly homogenized and stable pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; no habit forming.

ADRENALIN

[The Parke, Davis & Co. Brand of Epinephrin, U S P.]

IT IS not alone by restoring heart action in cases of apparent death from shock that Adrenalin has earned its reputation as a life-saver. In cases of collapse when the heart fails because of ebbing stimulus, Adrenalin supplies that stimulus by its direct cardiac action and by increasing the blood-sugar—glycogenolysis. And in many a less extreme case (of asthma for example) Adrenalin has rendered the patient's life endurable and prolonged it for years.

It is in daily demand for the reduction of inflammatory conditions of the mucosa—in eye, nose, throat and genito-urinary practice, also for its styptic effect in hemorrhagic conditions, and as an aid to the economical and satisfactory use of local anesthetics.

Adrenalin was made available to the medical profession by Parke, Davis & Co. in 1901 as a result of researches begun in our laboratories in 1900, and was the first hormone ever isolated from an animal organ.

Literature will be supplied to physicians on request

ADRENALIN (EPINEPHRIN, P. D. & CO.) IS INCLUDED IN N. N. R. BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION

Has Every Requirement for Infant Feeding

PURITY, digestibility and controlled uniformity are absolute essentials in cow's milk for infant feeding. Unsweetened, evaporated Carnation Milk has each of these requirements.

Carnation field men constantly inspect the selected herds which supply Carnation Milk. The purity of Carnation is ensured because it is handled with scrupulous care, thoroughly sterilized and protected by air-tight sealing.

There is great value in "homogenization" an important part of the Carnation process. Butter-fat particles are broken down, a finer, softer curd is formed making Carnation especially easy to digest.

Carnation Milk banishes the danger of upsets caused by milk of varying quality. Its butter-fat content is never less than about 7.8 per cent. Accurate dilution to the desired richness is easily obtained.

Pure, wholesome, safe, dependable, economical, everywhere obtainable, Carnation Milk is especially valuable to the medical profession.

"From Contented Cows" **Milk** Produced in Canada

The Audotor Tends to Correct Common or Progressive Deafness

A RECENT school survey was quoted by a well-known Medical Journal as indicating that some three million children were expected to show defective hearing when subjected to test.

One can hardly expect a child to either progress rapidly at school or be entirely happy at play if handicapped by poor hearing but unfortunately many are so afflicted.

The Audotor is recommended as a corrective agent in cases of middle ear deafness among children or adults.

It produces rhythmic air wave vibrations of inaudible frequency, periodic exposure to which has a tendency to both increase and sustain the patient's ability to receive and recognize conversational tones.

Systematic treatment in cases where it is indicated is resulting in improvement sufficiently lasting to be considered highly desirable by both physician and patient.

Further particulars in pamphlet form will be forwarded upon request.

IMPORTANT to PHYSICIANS ESPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponda's Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician but lacerations leucorrhoea, gonorrhoea prolapse post-operative and post-confinement treatment, and uterine hemorrhage are some of the conditions in which Ponda's Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponda's Tampons.

Ponda's Tampons are packed in six tampons to a box and are made in the following medication:

Full information and samples will be gladly furnished to physicians addressing us on their own stationery

Erysipelas Antitoxin

*reduces the patient's period
of disability by more than 50%*

ERYSIPELAS Streptococcus Antitoxin Squibb is prepared according to the principles developed by Dr Konrad E Birkhaug. It is the only Erysipelas Antitoxin now available which is manufactured under license from the School of Medicine and Dentistry, University of Rochester, Rochester, N Y. It is prepared and standardized by methods approved by the University, and has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

Each lot of this Antitoxin is submitted to the University of Rochester for test and approval before its distribution.

The use of Erysipelas Antitoxin in adequate dosage quickly relieves the toxic depression, reduces the temperature, pulse and respiratory rate, dispels the rash, promotes absorption of the œdema, reduces the patient's period of disability by more than 50 per cent, and reduces the mortality rate by even greater percentage.

The advantages of the use of Erysipelas Antitoxin to the hospital are, the reduction of the average period of hospitalization, with its consequent reduction in contagion and reduction of nursing personnel. In addition there is a notable saving of bed linen, due to the fact that ointments and similar local applications destructive to linen need not be used.

ERYSIPELAS STREPTOCOCCUS ANTITOXIN SQUIBB is supplied in concentrated form only, and is dispensed only in syringes containing one average "Therapeutic Dose."

*The "Priceless Ingredient" of Every Product is the
Honor and Integrity of its Maker*

An important recent development in infant feeding

*The colloidal action of Knox
Sparkling Gelatine is particularly
desirable in the baby's diet*

The colloid-chemical power of gelatine has been proved by Drs. Alexander, Bogue, Downey and other authorities. Gelatinized milk is being used by many physicians and in many institutions. It is more easily digested and absorbed. It increases the available nourishment of the milk mixture. Because it prevents the formation of large curds, it helps overcome regurgitation and vomiting. It is useful in the diet of infants with curdy stools, diarrhoea, constipation, colic or excessive gas formation.

In addition to its proved value in infant feeding, Knox Sparkling Gelatine is an important adjuvant in the diabetic diet where it increases protein content and satisfies the craving of the patient for bull in his food. In liquid and soft diets, Knox Sparkling Gelatine adds variety to the menu with dozens of dainty appetizing dishes.

For 40 years Knox Sparkling Gelatine has been our one standard product. From raw material to finished package, every process in its manufacture is subject to constant chemical and scientific control. Knox Sparkling Gelatine is all pure gelatine, unbleached, unflavored, free from sugar.

Valuable dietary information available

Noted dietitians have prepared the following booklets, setting forth the value of Knox Sparkling Gelatine in medical practice, and offering many appetizing recipes for its use in the various prescribed diets. Data on laboratory analytical tests is also available. Simply check the coupon below and mail it to us.

COUPON

All gelatines are not alike. Many have added acid, flavoring and coloring matter. In the form of ready prepared dishes, they contain as high as 15 per cent carbohydrates.

Knox Sparkling Gelatine is a product in its purest form, particularly suitable where carbohydrates and acids must be avoided. It contains more than 80 per cent pure protein (4 calories per gram), and has the same nutritive value as milk.

Specify Knox when you get your gelatine and you will protect the patient from harmful substitutes for his dietary purposes.

KNOX GELATINE LABORATORIES,
150 Knox Avenue,
Johnston, R.I.

Please send me, without obligation or expense, a booklet which has marked value for diet and medical purposes on clinical gelatine, as follows:

- ☐ Tying the Necessity of the use of Gelatine
- ☐ Diet in the Treatment of Diabetes
- ☐ The Value of Gelatine in Infant and Child Feeding
- ☐ The Health Value of Knox Sparkling Gelatine

Gardenal

Designates the Phenyl-ethyl-malonylurea manufactured by Messrs Poulenc Freres of Paris. It has become important as a remedy in the various conditions of nervous excitation. Its never failing effect particularly in the treatment of Epilepsy enhances the high quality of GARDENAL.

GARDENAL is supplied in tubes of 20 compressed tablets of 10 centigrams (1 1/2 grain), also in tablets of 05 and 01 centigrams (3/4 and 1/6 grain), in powder form containers of from 1/2 to 3 oz

Soneryl

Butyl-ethyl-malonylurea, a new hypnotic less toxic, yet more active, than Veronal. Soneryl offers the advantage of a narcotic effect in small doses associated with a sedative action which render it useful in those insomnias caused and prolonged by pain.

SONERYL is supplied in tubes of 20 compressed tablets of 10 centigrams (1 1/2 grain), in powder form containers of 1/2 oz and 1 oz.

Thyro-Ovarian Co. (Harrower) Is Different

—it is different, not because it contains thyroid, ovarian substance with corpus luteum, and whole pituitary. That alone would not account for its result-giving qualities. The real reason for the difference is that these ingredients are outstandingly potent. Take, for example, the ovarian substance. This has an exceedingly high lipochrome content, as shown by its colour—a very deep yellow. To make this possible a special defatting process is employed, the usual fat solvents not being used. If the residue extracted by any of the usual fat solvents is injected into animals, an immediate stimulation is manifested. This proves that part of the active principles remains in the residue, and is therefore lost. Injections of the residue separated by the Harrower process do not stimulate the organs. In other words, Harrower's ovarian substance contains all of the active principles. This is one of the reasons why Thyro-Ovarian Co. (Harrower) leads the way in the treatment of amenorrhea, dysmenorrhea, and other menstrual irregularities. Remember it! Thyro-Ovarian Co. (Harrower)—No 4 on our list.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed

solely to this *Journal*.

COPYRIGHT Matter appearing in the *Journal* is covered by copyright but, as a general rule no objection will be made to the reproduction in reputable medical journals of anything in these columns, provided proper credit be given

MANUSCRIPTS Should be typewritten, double spaced, and the *original* copy submitted to the respective Editorial Boards.

ILLUSTRATIONS Will be paid for by us when satisfactory photographs or drawings are supplied by the author. Negatives are not acceptable. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct and preferably black and on glazed paper, drawings should be made in india ink on white paper. For illustrations requiring cuts the best copper plate is used and all are printed on glazed paper. The *Journal* reserves the right to return photographs which are not satisfactory. Contributors are respectfully requested to limit illustrations to such as are absolutely necessary.

REPRINTS TO CONTRIBUTORS These may be ordered from the printers upon the form submitted with the galley proof.

ADVERTISEMENTS

First advertising forms go to press thirty days in advance of the date of issue. In forwarding copy, time must be allowed for setting up and submitting proof. Advertising rates on request.

N B —We exclude from our columns all known questionable advertisements and appreciate notification from our readers relative to any misrepresentation.

CLASSIFIED ADVERTISEMENTS are payable in advance. To avoid delay in publishing, remit with order. Advertisements under the following headings cost \$2 00 for each insertion of 40 words or less, additional words 5 cents each.

“UT DESINT VIRES”

AGAROL is the original Mineral Oil—Agar Agar Emulsion and has these special advantages

Perfectly homogenized and stable pleasant taste without artificial flavoring—freedom from sugar alkalies and alcohol no contraindications no oil leakage no griping or pain no nausea or gastric disturbances no habit forming.

In overcoming the cathartic habit so often a corollary of chronic constipation, the laudable endeavor is no longer sufficient excuse for “the lacking strength”

It has been repeatedly demonstrated that Agarol does tend to restore the natural peristaltic impulse, that dosage can be decreased as improvement takes place, and the patient frequently freed entirely from the great American habit of “the daily pill”

Try it on your most confirmed addict!

OVALTINE

When Sleep is Difficult

THE especial value of "Ovaltine" for this purpose lies in the fact that it can be given with minimum disturbance where there is impaired digestive function, a condition often met ineffectively by allowing the patient to go hungry

"Ovaltine" excites little digestive activity creates neither distress nor discomfort and promotes the digestion of other forms of nourishment taken in conjunction with it

Taken last thing at night before retiring "Ovaltine" exercises a pronounced sedative effect and one that is natural in every sense. It has a pleasantly soothing action on the stomach and nervous system, does not occasion constipation and promotes healthful sleep without resource to hypnotic drugs

A delicious concentration of malt, milk and eggs in the form of golden granules which dissolve instantly in milk

A liberal supply for clinical trial with full descriptive literature will be sent free to medical men on request

EAD'S Dextrin-Maltose, cow's milk and water, proportioned to suit the individual requirements of the infant, has given good results for many years

Nor has it been in the occasional case, but the *majority*, normal and difficult alike, that reflects the benefits of this carbohydrate (Dextrins and Maltose) combined with cow's milk and water to constitute the infant's diet

Infants on such a formula usually make satisfactory gains in weight. More, this weight represents sound musculature and not a mere "water logging" of the tissues such as especially occurs in highly sweetened mixtures

There is a minimum of nutritional disturbances from the use of Mead's Dextrin-Maltose, due to its larger absorption limits and ease of assimilation

It is invaluable to use with protein milk in cases recovering from attacks of fermentative diarrhoea, for it places the least tax upon the digestive tract of the infant

Mead Johnson & Co.
of Canada, Ltd
BELLEVILLE, ONTARIO

**MEAD'S
DEXTRI-MALTOSE**

"The different carbohydrates show different tendencies to fermentation. Milk-sugar ferments most easily, less easily the cane sugar, and least the dextrin-maltose preparations"

~ ~ ~

"Infants will tolerate a much higher mixture of maltose and dextrin than either lactose or cane sugar"

~ ~ ~

"It is of great importance that this maltose and dextrin should be derived properly (not by the acid process, but in a natural way) by the action of the enzymes of sound barley malt upon cereal starch"

~ ~ ~

"Malt sugar (dextrin and maltose) seems to be more easily digested and better taken care of by infants having had much digestive trouble"

"Feeding the majority of Bottle Babies" gives the advantages of the use of Mead's Dextrin-Maltose for infant feeding. Send in request with sufficient samples for trial purposes

Royal College of Surgeons England

EXAMINATIONS IN CANADA

First Professional Examination for the Diploma of Fellow TORONTO - JULY or AUGUST, 1929*

Arrangements have been completed by the Canadian Medical Association whereby the Royal College of Surgeons of England, will conduct in Canada the "Primary" examination in Anatomy and Physiology leading to the

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

The examinations, both written and *viva voce*, will be held by two examiners in each subject sent from England, and one assessor in each subject who is resident in Canada, but appointed for the purpose by the Royal College

A candidate for examination must deliver to the General Secretary of the Canadian Medical Association prior to April 1, 1929, for transmission to the Secretary of the Royal College of Surgeons, the following certificates

- 1 Of matriculation at a "recognized University",
- 2 Of having completed the examinations in Anatomy and Physiology for degrees in Medicine and Surgery of a "recognized University",
- 3 Of having dissected in a "recognized" Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a "recognized" Medical School

- 4 Of having attended in a "recognized" Medical School or Schools —
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall individually be engaged on the necessary experiments manipulations etc but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
 - (e) a course of Histology

The fee for examination or re-examination shall be \$100 00

The Final Examination for the Fellowship is held only in England and candidates for admission to that examination must have passed the Primary Examination and hold the Diploma of Member of the Royal College of Surgeons of England or have held for not less than four years a degree of a "recognized University" registrable on the Medical Register of Great Britain

Scientific control in local applications

Have all kinds of ULTRA-VIOLET the same effect?

NO, for some will cure rickets—others will not—some will sunburn—some won't. The reason for the difference between the ultra-violets is the wave length. Clinical evidence suggests strongly that rays from mercury vapor quartz lamps are of considerable value in certain forms of disease.

"Ultra-violet light from the air-cooled mercury vapor quartz lamp is a specific in tetany, rickets, and spasmophilia, and is very valuable as a general tonic in depressed bodily states such as anorexia and some cases of anemia, and in poor nutrition." The Atlantic Medical Journal, Vol XXXI, No 8, May, 1928, pages 537-542.

The KROMAYER LAMP is for irradiating small local areas and cavities. It assists materially in the successful application of rays to those conditions for which it is indicated.

The Vital Element of the KROMAYER LAMP

If there were no other advantages in the KROMAYER LAMP—if the mechanical excellencies that make for scientific precision and utmost convenience were eliminated—there would still remain one strong reason for its use—the HANOVIA Burner.

This burner is of the entire quartz mercury anode type, and is manufactured completely by Hanovia.

Each burner must pass a rigid test in the Hanovia laboratories, to insure the highest intensity and the longest service.

The economy of the HANOVIA Burner is apparent in its low consumption of current.

Further eventual economy is afforded by the ingenious construction which permits the repair of old or broken burners.

Character

When buying bonds for investment two factors should be taken into consideration -

FIRST—Property values, revenue producing powers and other tangible elements of security,

SECOND—The character and experience of the investment house which sponsors the issue

Experienced investors everywhere recognize that the second factor is just as important as the first

A list of sound bonds with full information will be provided on request

CARCINOMA AND ULCER OF THE STOMACH*

By E M EBERTS, M D

Montreal

BELIEVING this Association to be the proper channel through which to appeal to the profession of Canada, I have had the temerity to ask for a place on the program, in order to urge again the necessity for the earlier recognition of organic lesions of the stomach, especially carcinoma, and to plead for an intensive renewal of our efforts in this direction.

I am aware that this is a well-worn subject, by many it will be thought to be a threadbare subject, but the fact remains that cancer of the stomach is seldom recognized soon enough to render radical operation permanently effective. While it is true that in the early stages cancer of the stomach is often a silent affection, there are undoubtedly many cases in which a comparatively early diagnosis could be made, were it customary to submit every case of gastric disorder to a searching investigation upon the first appeal for treatment. It is the duty of the practitioner to exclude cancer as a cause of the symptoms before prescribing a course of medicinal or dietetic treatment of any duration, yet, in the history of cancer cases it is rarely recorded that, as soon as the complaints were laid before the physician, a test meal was administered and the stomach tube employed, the stools examined for occult blood, or an x-ray examination made. And, in the majority of cases, surgical opinion is sought only after the symptoms are no longer relieved by regulation of the diet and the administration of alkalies or other drugs. In a series of 48 cases of carcinoma of the stomach operated upon by me at the Montreal General

Hospital, gastric symptoms had been present in 30 for a period of more than six months before the true nature of the affection was recognized. Within the past six months there have come under my notice three cases of cancer of the stomach in which the subjective symptoms had for some months been relieved by rest, Sippy diet, and Sippy powders, cases in which a definite diagnosis between cancer and ulcer could not be made upon x-ray examination. These months of palliative treatment represent a loss of very valuable time, time which perhaps ultimately determines whether such patients after operation do or do not make permanent recoveries.

Having in mind the possibility of cancer, one should, in the clinical investigation of gastric cases, inquire especially into

(a) The *duration* of the symptoms complained of and the type of symptoms assembled under the term "indigestion." Pain, it should be noted, is exceptional, the complaint being rather of discomfort after food.

(b) The *appetite*. Anorexia, or at all events a variable or diminished appetite, is suggestive of cancer. In confirmation of what all have from time to time observed, however, Lenoir and Liege¹ have reported an interesting series of cancer cases in which the appetite was not only maintained, but increased.

(c) The *nutrition*. As time passes, cancer patients become aware of loss of strength and loss of weight, signs of failing nutrition.

(d) *Gastric analysis*. In 1879, Van der Velden first taught that the absence of free hydrochloric acid was a diagnostic sign of cancer, and many clinicians still believe that if free hydro-

*Read at the annual meeting of the Canadian Medical Association, Charlottetown, P.E.I., June 20, 1928.

chloric acid is detectable in the stomach contents cancer cannot be present. A résumé of recent publications, however, indicates that free hydrochloric acid is present in about half of the cases of gastric cancer. In my series the percentage was 25. While, therefore, the absence of free hydrochloric acid, in combination with other signs and symptoms, is strongly suggestive of a malignant growth, the presence of free hydrochloric acid by no means precludes the possibility of cancer.

It is now known that achlorhydria is the result of three factors

(1) The destruction of the hormone-bearing mucous membrane of the pyloric canal and pyloric antrum. (In the typical scirrhus carcinoma of the pyloric canal and antrum one would expect the reduction in hydrochloric acid secretion to progress *pari passu* with the destruction of the hormone-bearing mucous membrane. And this is probably what actually occurs.)

(2) The general bodily depression due to cachexia—the toxic factor.

(3) The clogging of the secretory crypts with excessive mucus.

Achylia gastrica is also met with in pernicious anemia, chronic gastritis, and atrophy of the gastric mucous membrane. Friedenwald and Brown² studied 38 cases of cancer in organs other than the stomach (breast, face, tongue, rectum, intestines, pancreas). The free hydrochloric acid content of the stomach was below normal in 55 per cent and absent in 37 per cent. The secretion of free hydrochloric acid was not augmented or re-established after surgical removal of cancer in a distant organ. Pauchet³ reported 21 cases of cancer of the stomach in which free hydrochloric acid was present. He concluded that the prognosis was much better in these cases than in those with achlorhydria. And this conclusion would accord with the fact that in early lesions free hydrochloric acid is present and that achlorhydria is evidence of extensive pyloric infiltration. On the other hand, Hartman's⁴ studies over a period of five years, on 80 resected cases of carcinoma, led him to believe that those with anacidity showed twice as satisfactory results as those in which free hydrochloric acid was present in the gastric secretion.

Mendel and Engel⁵ have presented evidence to show that the lactic acid in the gastric contents

in cancer cases is due to the action of a substance produced by the cancer itself on the glucose of the food.

(e) *X-ray examination*. This is in many cases of inestimable value, but, as we know from experience, the differentiation between early cancer and peptic ulcer by means of x-ray is not always possible. It is a very human tendency to assume that the lesser evil is the cause of the disorder and to settle comfortably into the conviction that the diagnosis of ulcer has been confirmed when, upon Sippy diet and alkali powders, the patient is relieved of all subjective symptoms.

(f) *Bleeding time*. According to Wicl,⁶ the bleeding time is normal in gastric cancer, but prolonged to seven or eight minutes in ulcer.

(g) *Bacteriology*. The sarcinae and Boas Oppleer bacilli which accompany prolonged stagnation are not found in early cancer cases. Meveringh⁷ has studied the bacteriology of the stomach and duodenum in ulcer and cancer, and has come to the conclusion that there is a rich flora in malignant disease, but a scanty one in benign ulcer. The bacillus coli is quite frequently absent in ulcer cases.

(h) *Sero-diagnosis of cancer*. Botelho, Roffo, and Kahn continue to publish work on the academic aspects of this question, but so far there does not seem to be any reliable test which can be applied clinically.

From the foregoing it is evident that there is as yet no reliable clinical sign or test for early cancer of the stomach. What, then, is the procedure in doubtful cases? I feel very strongly that, in all cases of chronic gastric disorder appearing after the age of forty, irrespective of whether the lesion is thought to be ulcer or cancer, the abdomen should be opened and the stomach directly examined. This can be done with a minimum of hazard, if local anesthesia is employed for the exploration. Even when the abdomen has been opened and the stomach exposed, there are often occasions when an experienced surgeon is unable to say whether the lesion is benign or malignant. Such an eminent authority as von Haberer⁸ admits that in 5 per cent of ulcer cases he could not be sure on exposure that cancer was absent. Finsterlin⁹ reports that in a series of 145 cases in which resection was performed for supposedly simple ulcer, 21.4 per cent were proved histologically to be cancerous.

It would seem fitting to say something here upon the relation of cancer to chronic peptic ulcer. During the past five years many important papers have been published on this point, but the opinions expressed have been very divergent. There are three main aspects of the subject.

1 Can a gastric cancer be converted into a gastric ulcer? The remarkable case reported by Thalheimer and Wilensky¹⁰ apparently answers this question in the affirmative. They describe a specimen showing a callous ulcer and multiple cancerous metastases, and present very convincing evidence that the ulcer was formerly a cancer and that the malignant tissue had been completely digested away.

2 What percentage of cases of cancer of the stomach originate in peptic ulcer? Those qualified to answer this question do not agree. Estimates vary from zero to 71 per cent. The latter figure is taken from the much discussed contribution of Wilson and McCarthy.¹¹ Expert statistical study of the available data would probably be needed to give an accurate estimate of the percentage. Certainly it cannot be very high, possibly from 5 to 10 per cent.

3 What percentage of ulcer cases become cancerous? (This question would, upon a superficial view, appear to be the same as No. 2. To illustrate the difference it might be proved that all carcinomata originated in ulcer, but this would not prove that all ulcers become cancerous.) McCarthy¹¹ affirms that 68 per cent of the gastric ulcers in his series were associated with cancer, while Ewing¹² says that anything above 3 per cent is a high figure. Finsterlin's⁸ figure is 26.6 per cent, Orator's¹³ 10 per cent in 700 cases. Eusterman¹⁴ maintains that every ulcer is potentially a cancer.

Intensive investigations have been carried out along various lines: (1) animal experimentation, (2) comparison with other cancerous and ulcerative lesions in human cases, (3) statistical studies of human cases, (4) gross anatomical and microscopical studies of human cases, and (5) clinical studies.

ANIMAL EXPERIMENTATION

Hemmeter, Futterer, and Maniscalco¹⁵ have, by irritation of artificially induced ulcers, produced in animals interesting growths described by them as malignant. Ewing,¹⁶ however, points

out that these growths have lacked the progressive character of cancer.

COMPARISON WITH LESIONS IN OTHER ORGANS

Cancer and ulcer may co-exist in the lip, tongue, tonsil, larynx, œsophagus, rectum, or in x-ray dermatitis, but in these lesions the ulceration invariably follows the malignant growth. On the other hand, ulcers may exist for years in the duodenum, where cancer is a curiosity, lupus is complicated by cancer only after an average duration of 30 years, and in varicose ulcers malignant change is met with but rarely, and then as a rule only in the most chronic cases. While this evidence is against the frequent transformation of ulcer into cancer, it must be remembered that the stomach may possibly be an exception.

STATISTICAL STUDIES

R. Williams¹⁶ has made a statistical investigation of the age incidence and location of gastric ulcer and cancer and the occurrence of cancerous degeneration in ulcers elsewhere in the body. His conclusions are against a great frequency of carcinomatous change in peptic ulcer. Bamberger¹⁷ followed for a considerable period 1,025 cases in which gastro-enterostomy had been performed for gastric ulcer. Cancer developed in 22 cases (2.1 per cent). Von Eiselsberg in his own cases observed 5 per cent, Hirschfeld¹⁸ from 5 to 6 per cent. These figures might very well, and undoubtedly do, include cases in which cancer was present at the time of operation, but not recognized. Although it cannot be proved to be true, there would appear to be substantial clinical support for Paterson's contention that, following gastro-enterostomy and the admittance of pancreatic secretion into the stomach, there is conferred upon the stomach the same immunity to cancer as is enjoyed by the small bowel.

PATHOLOGY

Hauser's¹⁹ original description of *ulcus carcinomatosum* has been unsurpassed in modern literature. Of the later descriptions, Ewing¹⁶ conforms to Hauser's. Cancer is seen on the pyloric side of the peptic ulcer. The base of the ulcer is covered by a shortening of the peritoneal side.

the serosa and approximation of the lymph nodes by cicatricial contraction, these changes are more marked in the presence of secondary cancer. The lymph-nodes become large and hard. Metastases occur, practically always, in the liver, although many cases die from pyloric obstruction while the lesion is still confined to the stomach and proximal glands. Perforation of a cancerous ulcer may terminate the case.

To Hauser¹⁹ again we owe the best description of the histological features of true "ulcerocancer." The process begins in the edge of the ulcer nearest to the pylorus and consists of a downward growth of atypical glands, which soon break up into irregular alveoli lined by atypical cylindrical or cuboidal cells. The muscle tissue layers of the muscularis mucosa and of the true muscle coat show a definite rearrangement, and the callous ulcer base is free from cancer, unless it is invaded from the peritoneal cavity. (Hemmeter²⁰)

If all pathologists apply these criteria as standards of malignancy occurring in peptic ulcer, there would probably be a closer agreement on the question of the frequency of this lesion.

CLINICAL STUDIES

A résumé of the clinical aspects of a series of gastric cases does little to assist in the perplexing problem of the possible origin of cancer in ulcer. On the contrary, it seems to make the question more difficult, since one is made to realize that a clinical differential diagnosis between an early (i.e., curable) cancer and a chronic peptic ulcer is frequently impossible. We have learned by bitter experience the importance of diagnosis at the earliest possible moment. The realization, too, that in many cases an absolute diagnosis can be arrived at only by histological study, prompts the surgeon to urge early laparotomy in cases of gastric disease. The clinician's duty is not only to name the disease, but also to cure it, and of these two duties the latter is the more important. Perhaps one can illustrate best by analogy the importance of early diagnosis of cancer of the stomach. The efficacy of early operation in cancer of the breast would appear to be beyond question. In this outward and visible form of malignant disease early detection is possible, and, where operation antedates glandular meta-

stasis, the percentage of permanent cures is very high, being at least 75 per cent. On the other hand, in all cases of breast cancer with axillary metastases, from 77 to 80 per cent die of cancer within three years. With the methods at present at our disposal it may be too much to hope that a diagnosis of cancer of the stomach can be frequently made while the disease is in the primary stage, that is while it is still confined to the stomach, but, if a concerted effort on the part of the profession, such as I have suggested at the opening of this paper, should result in the detection of all cancers of the stomach even in the stage of proximal glandular metastasis, radical excision would, I believe, offer as good a prospect of permanent cure as in breast cancer of the same status. This would mean that in from 20 to 23 per cent of cases of carcinoma of the stomach in the early second stage, permanent cures following radical excision might be expected. Even this result, excluding as it does the cases in which lymph-glandular involvement has not yet occurred, would be a tremendous advance upon present results. But is it not possible to eclipse the prognosis which is warranted by the diagnosis of cancer of the stomach in the stage of early glandular involvement? It undoubtedly is, and in time will be realized, but only at such time as the practitioner is prepared to submit promptly to the surgeon for radical treatment all gastric lesions, whether diagnosed as cancer or ulcer. In support of this view one can but refer again to the experience of Finsterer, von Haberer, and others, which proves beyond question that a large percentage of cases can be adjudged cancer or ulcer only by the pathologist. In these cases the cure precedes the diagnosis in fulfilment of the more pressing urgency.

To revert to the present status of diagnosis and the surgical results, I feel very strongly that, in spite of the frequency of recurrence following gastrectomy, all cases of cancer of the stomach, however "inoperable" they may appear to be on physical examination, should be explored, and that, in the absence of infiltration of the pancreas, involvement of the transverse colon, or metastases in the liver, resection should be undertaken. Quite apart from any prospect of permanent cure, radical excision gives to the obstructive case an extension of life prospect of approximately two years, whereas without opera-

tion it would be about six weeks. Furthermore, as is the rare experience in the treatment of advanced cancer of the breast, excision in an apparently hopelessly advanced case may give an even longer respite. In illustration of this occasional brand that is saved from the burning I would cite briefly the following case.

C. L. W., male, aged 49, a resident of Granada, B. W. I., was admitted to the Montreal General Hospital (service of Dr. H. A. Lafleur) on December 11, 1923. The patient presented the usual symptoms of pyloric obstruction, namely, discomfort after food, coffee ground vomitus, loss of weight, and loss of strength, symptoms which had been present for three months. On examination of the abdomen there could be seen and felt a large tumour in the pyloric region. The x-ray confirmed the diagnosis of extensive pyloric cancer with 48-hour retention. Under ether anaesthesia subtotal gastrectomy, with removal of the subpyloric lymph nodes as well as the lymph nodes in the gastrohepatic omentum (the latter containing metastases), was performed, concluding with a retrocolic anastomosis between the gastric stump and the jejunum (Polya). Recovery was uneventful. After a lapse of four and a half years the patient is in normal health and throughout this period has been able to carry on without interruption his duties as a government official.

Finally, as an additional plea for radical excision even in advanced cases, subject of course to those restrictions already mentioned, one should point out that recurrence is almost invariably in the liver and runs a rapid and usually painless course. Recurrence in the stomach itself is unusual, and the patient is spared the distress of persistent vomiting and a death from starvation.

Time will not permit of a discussion of the technical procedure of gastrectomy. The risks are those of intestinal resection generally and post-operative deaths are due to pneumonia, not to peritonitis. Under local infiltration of the abdominal wall for the incision and of the root of transverse mesocolon and gastro-hepatic omentum along the lesser curvature at the junction of the fundus with the oesophagus, or by the use of splanchnic anaesthesia after the abdomen has been opened, resection can be carried out without discomfort to the patient. This

method of anaesthesia permits the inclusion in the operable class of a large number of patients who, because of the cachexia and extreme anaemia, could not be given a general anaesthetic without too great hazard.

Attention was then drawn to an exhibit of a series of casts of stomach lesions, both cancer and ulcer. These beautiful preparations were the work of Miss Hortense Douglas, artist to the Montreal General Hospital. They were prepared with infinite care and fidelity and undoubtedly were a great advance upon the actual specimens fixed and preserved by chemical agents.

Acknowledgement was made to Drs. Bazin, Barlow, and Howard for the loan of specimens from their services.

The specimen of benign and malignant papilloma was rather unique. This was a case where the early symptom (haemorrhage) was erroneously attributed to high blood pressure. Had the case been investigated radiographically three years ago and operation performed, there was no doubt that the diffuse papillomatosis would have been found to be wholly benign. (X-ray diagnosis of both benign and malignant papillomata was made by Dr. Ritchie, radiologist to the Montreal General Hospital.)

"Whoever is to acquire a competent knowledge of Medicine ought to be possessed of the following advantages: a natural disposition, instruction, a favourable position for the study, early tuition, love of labour, leisure. First of all, a natural talent is required, for when nature opposes everything else is vain, but when nature leads the way to what is most

excellent, instruction in the art takes place, which the student must try to appropriate to himself by reflection, becoming an early pupil in a place well adapted for instruction. He must also bring to the task a love of labour and perseverance, so that the instruction taking root may bring forth proper and abundant fruits."—Hippocrates

—OVER-

THE TREATMENT OF PERNICIOUS ANÆMIA*

BY DUNCAN GRAHAM, M B ,

Professor of Medicine, University of Toronto

TWO years ago, on a similar occasion, I had the honour of addressing the members of this Association on the subject of Addison's "pernicious" anæmia.¹ In discussing the treatment of this disease at that time I stated that Minot² had recently reported favourable results from the feeding of liver. Since then the results obtained by Minot and Murphy have been fully confirmed by a number of clinicians, both on this continent and abroad.

Successful as the feeding of liver is in the treatment of pernicious anæmia it does not follow that other important features of our former regime of treatment can be disregarded and their value lost sight of. Adequate rest in bed, with controlled rest and exercise to avoid fatigue, attention to possible foci of infection, and the administration of hydrochloric acid are just as important to-day as before the days of liver feeding. Early diagnosis, the removal of foci of infection, and adequate rest in the early stages of treatment of pernicious anæmia are the three principal requirements if the best results are to be obtained from the feeding of liver.

Why are these important? In addition to the signs and symptoms of anæmia present, the result of disease of the hæmatopoietic system, signs and symptoms are found characteristic of disease of other systems of the body, more particularly of the digestive and nervous systems, *e g*, periodic sore tongue, and persistent numbness and tingling of the extremities, indicating that the disease is not confined to the blood-forming organs. As these latter symptoms often appear before significant signs of anæmia develop, and constitute the chief complaint of some patients, failure to recognize them as possible manifestations of pernicious anæmia leads to a false diagnosis and the treatment of the case for some indefinite condition affecting the digestive or nervous systems. As a result, the associated changes in the nervous system are allowed to advance to a stage where complete recovery of

function is impossible, despite the cure of the anæmia, or complete anorexia develops, often associated with other distressing gastrointestinal symptoms, which makes the institution of liver feeding very difficult.

The removal of foci of infection is important for several reasons. (1) Focal infection is known to affect the bone marrow and cause an anæmia of the secondary type. The presence of a focal infection in patients suffering from pernicious anæmia is not only an additional cause for the production of anæmia but, more important, liver therapy is of little value in the treatment of anæmia due to focal infection. The response of pernicious anæmia patients to liver feeding is less satisfactory in the presence of a focal infection, (2) Foci of infection may affect all systems of the body, and structures like the spinal cord, the tongue, and possibly other organs already affected by the existing pernicious anæmia, are more susceptible than healthy tissues to the toxic effects of a focal infection, and the improvement in symptoms caused by these changes following liver treatment is naturally slower and often incomplete. Experience in the treatment of pernicious anæmia cases has shown that symptoms apparently relieved during treatment may reappear with the development of an intercurrent infection. There can be no doubt, therefore, as to the importance of the eradication of all foci of infection at a favourable time during the course of treatment.

Lastly, the importance of rest.—In patients suffering from any form of anæmia, fatigue both mental and physical is often one of the major complaints. Rest is the best form of treatment for fatigue from any cause, and the prevention of fatigue by absolute rest, followed by controlled rest and exercise periods later, is considered essential for the successful treatment of disturbances of function due to lesions of the nervous system, such as are so commonly found in pernicious anæmia. In this disease rest is necessary in treatment, firstly, until the anæmia is improved to a degree where exercise may be taken without fatigue, and secondly, until an adequate time has been given for sufficient im-

* Read at the annual meeting of the Canadian Medical Association, Charlottetown, P.E.I., June 20,

provement to take place in the lesions affecting the nervous system to allow of a moderate degree of activity, both physical and mental, without the development of fatigue

GENERAL PLAN OF TREATMENT

All patients suffering from pernicious anæmia should have absolute rest in bed and freedom from all responsibilities at the beginning of treatment. If gastrointestinal symptoms are not marked, and the patient is able to eat, he should be given a balanced diet containing milk, green vegetables, fresh fruit, and red meats, including, 150 to 240 grams (5·8 ounces) of liver daily.³ After a few days the appetite improves and the patient feels better. The slight fever, the sore tongue, and the bilirubinæmia present soon disappear. At the end of two weeks the percentage of hæmoglobin begins to rise, and a corresponding increase in the number of red blood corpuscles occurs. In our series of cases the increase in the hæmoglobin during the first month averaged 27·5 per cent, the highest being 64 and the lowest 10 per cent. In the second month, the increase averaged 20 per cent and at the end of three months of treatment the hæmoglobin was usually above 80 per cent and the red blood corpuscles more than 4,000,000. This improvement has been maintained without remissions for periods up to two years in patients following the treatment prescribed. All these patients received 150 grams of cooked liver daily. In a large series of cases reported by Minot and Murphy⁴ the average number of red blood corpuscles at the beginning of treatment was 1,483,000, at the end of two months 4,200,000, and in the cases which had adhered to diet, observed at the end of two years, the red blood corpuscles were more than 4,500,000. This group of patients received approximately 200 grams of liver daily. Although improvement in the anæmia during the first two months in their series of cases was a little more rapid than in ours, given 150 grams of liver daily, the latter quantity in our experience has been found sufficient to maintain the number of red blood corpuscles and the percentage of hæmoglobin at or about a normal level.

Liver may be served raw or cooked. It may be ordered as liver and bacon, or it may be ground to a pulp and the daily quantity given raw in fruit juice, or lightly cooked as liver soup, liver hash, croquettes or patties. If the preparation is varied from day to day little difficulty is experi-

enced in persuading the patient to take the prescribed amount. In patients with severe gastrointestinal symptoms, such as complete anorexia, nausea and vomiting, some difficulty may be found during the first few days of treatment. If one is persistent and succeeds in getting them to take liver in some form for three or four days, the serious gastrointestinal symptoms disappear, the appetite returns and, as Minot and Murphy have reported, they may become ravenously hungry. At the end of a week they are usually able to take a fairly liberal diet. The preparation of a surtable liver extract has greatly simplified the treatment of this type of case, as a dose of the extract, given in some fresh fruit juice, is usually retained. If no liver extract is available, liver soup or liver juice expressed from slightly cooked, ground liver may be given with the juice of an orange or grape fruit. It may be necessary to feed the patient through a duodenal tube for the first couple of days. In the past a few of these patients were tided over by transfusion, many, if not the majority, died.

In most cases at rest in bed distressing symptoms disappear in a week or two, and at the end of a month even peripheral nervous manifestations, such as numbness and tingling, especially if they have been of short duration, have disappeared. The patient feels well and wants to be up and about. In allowing him up, the avoidance of fatigue should be our chief concern in treatment. Patients with no symptoms referable to the nervous system may be allowed up after two weeks if the hæmoglobin is over sixty per cent. The amount of exercise should be increased daily, always within the point of causing fatigue, until the patient is able to resume work. Recovery from nervous manifestations appears to be dependent not only upon their severity but upon their duration, and improvement takes place slowly as compared with other symptoms. With liver treatment the improvement in the general condition of the patient, and the cure of the anæmia, are so rapid, in comparison with the usual results obtained from former methods of treatment, that patients are now allowed to become active, both physically and mentally, too early in treatment. Patients should have absolute rest for one month after the nervous symptoms have been relieved or become stationary, then rest and exercise should be controlled according to the severity and character of the symptoms. Once numbness and tingling have been relieved, fatigue from over-

activity, the development of an infection, or the interruption of liver treatment, have been in our experience the three factors responsible for their recurrence. In patients complaining of difficulty in walking, due to lesions in the posterior and lateral columns of the cord, almost complete recovery may take place, and the patient be able to walk without difficulty if the complaint has been of short duration. In long standing cases marked improvement may occur, but a definite disability remain. Hence the importance of the early recognition of the nervous manifestations of pernicious anæmia. A history of numbness and tingling, or the development of signs suggestive of *tabes dorsalis*, should be an indication for the most careful examination of the blood, to exclude or prove the presence of pernicious anæmia.

When a patient is taking the required amount of liver daily and not responding to treatment a focus of infection should be suspected. In the presence of an infection the response of the bone marrow to liver feeding is poor, the relief of symptoms is delayed, and in patients relieved of symptoms the development of an intercurrent infection, *e.g.*, tonsillitis, often causes a return of symptoms, such as numbness and tingling. Every case should be carefully investigated for possible foci of infection, particularly in the upper respiratory tract, and in the case of male patients in the prostate. If an acute or subacute infection is present local treatment should be given until the infection subsides and the general condition of the patient has improved, before suggesting removal by operation. If multiple foci of infection are present they should be removed gradually, otherwise severe reactions with exacerbations of symptoms may follow. Too often patients with several infected teeth are advised to have them extracted, and unless the dentist is warned he may remove them all at one sitting. The physician should supervise extractions, advising the removal of one in the beginning, and further extractions according to the reaction that takes place. Possible metastatic foci of infection in the gall bladder, appendix, etc., should not be forgotten. In patients adhering to treatment, but not improving, in whom no foci of infection have been found, continue the search for an infected focus.

In pernicious anæmia achlorhydria (not the result of the disease but probably a factor in its development) is always present. An attempt should be made to compensate for the deficiency

of hydrochloric acid in the stomach by the liberal administration of this acid, as recommended by Hurst. Treatment should begin with one drachm of dilute hydrochloric acid in a tumblerful of fruit juice sweetened with sugar, the patient being instructed to take one-third half an hour before each meal, one-third during the meal and one-third one-half hour after each meal. This dose should be increased until he is taking one and one-half to two drachms three times a day. He should be advised to drink the acid fruit juice mixture through a straw or, if taken in the ordinary manner, to wash the mouth with water. While it is true that the anæmia and the associated symptoms will improve without the administration of acid, it seems advisable to compensate for the acid deficiency by prescribing it in the dose recommended. Patients once accustomed to taking acid usually refuse to give it up.

Blood transfusions are seldom indicated. With the number of red blood corpuscles below a million, and nausea and vomiting present, a single transfusion of blood is often followed by an improvement in the general condition of the patient, which may tide him over until he is able to take an adequate quantity of liver.

A liver extract is now available as a substitute for whole liver. The active principle which is effective in the treatment of pernicious anæmia has been found by Cohn,⁵ an associate of Minot, to be present in a non-protein fraction of the liver. It is soluble in water, insoluble in ether, precipitated by alcohol, is free from lecithin and ordinary lipoids, and contains 7 per cent of nitrogen and only a trace of iron and sulphur. This extract, when prescribed with the diet recommended above, but without the addition of liver, has the same effect on the blood forming organs in pernicious anæmia as whole liver. In beginning treatment, Minot and his associates⁶ recommend a dose of extract equivalent to the amount derived from 500 to 600 grams of liver. Later, this may be decreased to the amount derived from 300 to 400 grams. We have found that this latter dose produces the same rate of improvement in the blood as 150 grams of whole liver. At the present time liver extracts prepared by a number of pharmaceutical firms are on the market. These extracts are not all of equal potency. Unless the physician is able to have the patient's blood examined daily during the first two weeks of treatment, to determine the reticulocyte response, and thereby test the

potency of the extract, he will be well advised to begin treatment with whole liver, or to prescribe only a liver extract from a batch known to be potent. This is particularly important in patients with marked gastrointestinal symptoms and a severe degree of anæmia.

A word with reference to the value of liver in other types of anæmia. The public, generally, know of the striking results obtained in the treatment of pernicious anæmia from the feeding of liver. To-day many people are taking liver because they are pale, and many physicians are prescribing liver in all types of anæmia. The feeding of liver has a specific effect on the bone marrow in pernicious anæmia,⁴ producing a temporary but prompt marked increase in the reticulocytes, followed by a rapid rise in the number of red blood corpuscles toward a normal level, which is maintained as long as the patient continues to take an adequate quantity of liver. No such reticulocyte response or rise in the number of red blood corpuscles occurs in the common secondary types of anæmia. No results are obtained in the treatment of secondary types of anæmia which justify the feeding of large quantities of liver.

Patients undergoing treatment for pernicious anæmia should return periodically for an examination of the blood. They should be questioned as to the amount of liver they are taking each day. Careful enquiry should be made as to the return of symptoms previously relieved by treatment, especially with reference to the early digestive and nervous manifestations of the disease. In one of our patients a sore tongue recurred when the red blood corpuscles were about normal in number. It was later found that this patient for economic reasons was taking

liver irregularly. Just as periodic sore tongue may occur in the beginning of the disease before a definite anæmia has developed, so it may antedate the development of anæmia in a relapse, and be the first indication that the patient is not receiving an adequate quantity of liver. Three factors appear to be chiefly responsible for the reappearance of anæmia, or the return of symptoms previously relieved by treatment, or the exacerbation of nervous manifestations that had become stationary. They are (1) an inadequate daily amount of liver, (2) infections, (3) activity beyond the physical or mental reserve of the patient. Hence the importance of periodic examinations to check the development of even mild relapses.

If the plan of treatment just outlined is followed, and the patient co-operates in the treatment, we are justified in concluding that the anæmia present in pernicious anæmia will be cured, that signs and symptoms not the result of structural changes in a stage beyond repair will disappear, and that the disease will remain under control so long as the patient takes the required daily amount of liver or suitable liver extract. The successful treatment of another disease has been accomplished.

"When we turn to chronic rheumatism the first thing that strikes the eye is the complexity of the picture. In this picture, however, certain features are found which resemble those of acute rheumatism: the disordered skin reaction, the disturbance of endocrine function, and the specific tissue reaction to low grade streptococci, namely, the nodule. Like acute rheumatism, these conditions—whether infective arthritis, fibrositis, or osteo-arthritis—must be looked upon as biological deviations, as system diseases. The first two have their seeds in early life, while the last may be a part of the general deterioration of advancing years affecting joints which have been weakened by strain, trauma, or infection, acting separately or together. In

the investigation of these diseases it is necessary to pay attention to the biochemical constitution of the patient, and deviations from the normal will often, if not always, be met with. The commonest are disturbances in sugar tolerance, alterations in the pH values of the body fluids, and abnormalities in the metabolism of calcium, phosphorus, and sulphur. The endocrine organs, and more particularly the thyroid gland, are as a rule at fault, hypothyroidism being associated particularly with fibrositis and chronic synovitis, and dysthyroidism with infective arthritis. Foci of infection are of great, but not exclusive, importance, and faulty elimination must also be taken into account."—*Brit M J*, 1928, i, 860

THE STUDY OF THE EFFECT OF VARIOUS AGENTS, CHIEFLY SUNLIGHT UPON THE SUSCEPTIBILITY OF RACHITIC RATS TO INFECTION

BY ELIZABETH CHANT ROBERTSON, M A , M B ,

Research Assistant, Connaught Laboratories University of Toronto

Toronto

THIS communication is a complete summary* of results obtained in a study of the effect of sunshine on rachitic rats, as measured by their susceptibility to infection. As the shorter ultraviolet rays in the sunshine improve the rickets in these animals, a brief comparative study, using the same test of susceptibility, of the effect of other antirachitic agents, *eg*, the mercury-vapour lamp (so-called artificial sunlight), cod liver oil, and irradiated ergosterol was undertaken. Similar experiments were carried out to determine if possible whether exposure to cold air was a factor in raising the resistance of these animals.

THE RATS†

Albino rats, twenty-five to twenty-seven days old, were used as the test animals. The diet and environment of the breeding rats were kept constant, in order to reduce to the minimum the variation in the amounts of vitamin D stored up during lactation. All the rats, except a few in the last experiments which were given a normal diet, were put on McCollum's rachitogenic diet 3143, as soon as they were received, and were kept on this diet for four weeks. At the end of this time their resistance to infection was determined.

THE INFECTING ORGANISM

A strain of *B. coli communis*, which had been obtained in a nasal culture from a normal rat, was used as the infecting organism. Eighteen hours' growths on plain agar slants were washed off with measured amounts of saline, and a small quantity of this suspension was injected into the peritoneal cavity. In the first ten experi-

ments (Table I and about 1/5 of those in Table IIa), all the rats in each experiment received the same amount of suspension. In all the later tests, each animal was given a dose proportional to its weight (0.003 c.c. per gram body weight). For example, a rat weighing 76 gm. would be given 0.23 c.c. of the suspension.

As the sun-exposed rats frequently weighed on the average a little more than the rats kept inside, they received larger doses, which made the test more severe.

From the results of a number of supplementary experiments, we believe that the rats, following the injection, die from a generalized infection. Post-mortem examinations, including blood cultures, were made on all the dead rats. When a capillary pipette was used to obtain the blood from the heart, practically 100 per cent of the dead rats showed pure cultures of Gram-negative bacilli. The biological and serological reactions of three recovered strains were studied and they were identical with those of the injected organism.

The results of the first 6 experiments,‡ which have previously been described in detail, are summarized in Table I. Twice as many sun-treated as inside rats survived the infection.

Table II (A) is a summary of the results obtained in 18 experiments in which was com-

pared the susceptibility of rachitic rats (1) exposed to the sunshine for the routine 2 hours per day (11 a.m. - 1 p.m.) for 4 weeks, (2) exposed for 15 minutes per day, 30 cm from a quartz mercury-vapour lamp for 4 weeks, and (3) kept inside in an animal room in which the windows were opaque, and the door provided with a screen, so that no direct sunlight reached the cages.

Table II (B) gives the details of one of the eighteen experiments which are summarized in Table II (A).

Of 105 sun-treated rats, 44 per cent survived as compared with 25 per cent of the 103 inside rats. In two individual experiments, a greater percentage of inside than sun-exposed rats survived, but in the other sixteen experiments, the sun-exposed showed the higher survival rate. As 38 per cent of the 101 mercury-lamp rats survived, it is evident that they did not withstand the infection as well as the sun-exposed rats. In 4 of the 18 experiments the mercury-lamp rats showed the highest survival rate. These rats exposed to the mercury-vapour lamp have less marked rickets than the rats exposed to the winter sunshine, and if the increased resistance is due to the healing of the rickets, one would expect the mercury-lamp rats to do the best, unless in addition to its rickets healing power the mercury-lamp has an injurious effect on the rats. It is suspected that the fifteen minute exposures were too long, for when two small groups of rats were irradiated for 7½ instead of 15 minutes they showed a degree of resistance equal to that of the rats put out in the sun. From a study of the literature, also, it seems probable that short exposures of 5 to 10 minutes per week are more beneficial, at least to normal human beings, than more frequent and longer exposures.

The rats that were put out in the sun were also exposed to the cooler outside air and any benefit which they obtained from the latter environment might explain the higher resistance rate of the sun-exposed as compared with the mercury-lamp-exposed rats. To determine if exposure to the air affected their susceptibility, rats kept inside, rats put out in the open air but protected by a rough shelter from the sun, and rats put out in the open air and sun were compared. Table III gives the results of this series of 10 experiments. It is evident that the sun-

January to May	72	26	64%	65

exposed rats survived in greater numbers than those kept inside. The survival rates of the rats exposed to the sun alone varied greatly in the different experiments. In three experiments they withstood the infection better than the inside rats and not as well as the sun exposed, but for the rest, they died more frequently than either of the other two types. The variations did not correspond with changes in the temperature of the outside air. When the results from all the experiments were added up, it was seen that the rats exposed to the sun alone did not show as high a survival rate as the rats kept inside. Consequently, it was concluded that the rats under the conditions of this experiment were not benefited by the outside air.

So far, most of the results had suggested that the increase in resistance ran parallel with the healing of the rickets. Whether a similar beneficial effect would follow the curing of the rickets by the addition to the food of small amounts of cod liver oil or irradiated ergosterol (which is vitamin D) was studied in the next group of rats. These experiments were not as satisfactory as the preceding ones, partly because for some reason the rats kept inside did not show marked rickets (some of the antirachitic food might have dropped through from the cages above), and partly because the results with the rats fed the antirachitic substances varied greatly in the different experiments. If the variations were overlooked and the total results of all experiments added up, it was seen that the curing of the rickets, whether by sun-

shine or irradiated ergosterol, raised the resistance equally well. Cod liver oil was less effective. These results are shown in Table IV.

Similar experiments should be repeated and additional ones, embodying some improved technique for the administration of the antirachitic material undertaken.

When rats fed a normal diet were placed out in the sun for the some two hours daily, they did not gain in weight as well as did similar rats given the same food but kept inside. At the end of the four weeks' treatment, these sun-exposed rats did not withstand the artificial infection as well as those kept inside. Apparently, therefore, exposure to the sun is not beneficial to normal rats. (See Table V)

TABLE V

May and June	25	14	44%	80

CONCLUSION

It has been found that exposure to the sun about noon for 2 hours daily during a period of 4 weeks markedly raises the resistance of young rachitic rats to infection. Of 263 sun-exposed rats, 57 per cent survived, and of 241 rats kept inside, 32 per cent survived. Normal rats, after such sun treatment, did not survive as well as similar rats kept inside. Exposure to the outside air with protection from the sun had no beneficial effect on rachitic rats. After these

rachitic rats had been given treatments extending over 4 weeks' time, in which they were exposed at a distance of 30 inches from a quartz mercury-vapour lamp for fifteen minutes daily, they showed a higher degree of resistance than corresponding rats kept inside, but not as high as such rats put out in the sun. Fifteen minutes is probably too long an exposure for these animals. Rachitic rats, fed small amounts of irradiated ergosterol, are less susceptible to artificial infection than such rats that have been given no antirachitic treatment.

CHRONIC CARBON MONOXIDE POISONING*

By J C S BATTLEY, M.B.,

*Instructor in Paediatrics, University of Western Ontario Medical School,
London*

CARBON monoxide poisoning is one of our most serious health problems. It is widespread and difficult to cope with, and comparatively little has been accomplished so far in its prevention. Since the discovery of fire, it has been a menace to man, and, as time has passed, it has become of more and more importance, until to-day it is involved in his very existence. Aristotle¹ referred to coal gas as a cause of death, and Livy described wholesale executions by suffocation from the gases of fires. Its path through the middle ages has been traced. By 1500 A.D. the symptoms of poisoning were known, and its importance as an industrial poison was recognized, and in the eighteenth century accurate observations of its effects were published. These effects had often been attributed to the work of demons and witches. It was first artificially prepared by Lassone in 1776, and for a time was thought to be identical with hydrogen. Much has been done to combat the more familiar form of acute poisoning, though deaths are on the increase.² It is with the problem of chronic poisoning that this paper deals.

NATURE OF THE GAS AND ITS DISTRIBUTION

Carbon monoxide is a colourless, odourless, tasteless gas, non-irritating, and chemically

inert, which is formed when incomplete combustion of organic matter takes place. Since combustion of fuels is far from complete, it follows that it is produced in large quantities and is widely distributed. It is present in the exhaust of all types of gasoline engines, it is formed when wood or coal is burned, it is found about blast furnaces, gas works, smelters, and in mines, it is produced in the firing of guns and in the explosion of military mines, it is even present in tobacco smoke. There are few industrial activities in which carbon monoxide is not encountered. The effects of chronic poisoning are insidious and slow in appearing, and depend upon exposure to low concentrations of the gas, extending over weeks or months. Damage may be done before the patient realizes he is in danger.

Carbon monoxide from automobiles on streets where the traffic is heavy is a menace to people in general. When one remembers that there is a motor car for every eleven people in Canada and for every five in the United States, with the number rapidly increasing, to say nothing of the many stationary gasoline engines in use, the extent of pollution of the air becomes apparent. Exhaust gas from the ordinary automobile contains 5 to 6 per cent of carbon monoxide. In the average private garage with the doors closed, and in which an automobile engine is running, a dangerous concentration of

* Read at the annual meeting of the Ontario Medical Association, Kingston, May 31, 1928.

gas is reached in three minutes, and asphyxiation may occur in five, followed by rapid death^{3,4}. The effect is much slower on the streets and in large public garages, where the concentration, although much less, may still reach a degree incompatible with health. In 1923, Henderson and Haggard,⁵ investigating the conditions in city streets, found that a stationary car with the motor running filled the air behind it at respiratory level with four to six parts of carbon monoxide per 10,000 of air. When running ten miles per hour, the occupants of a car thirty feet behind were surrounded by exhaust gas diluted to a concentration of one to two parts of carbon monoxide. One part in 10,000 was a frequent condition in streets where traffic was heavy, and in unusually congested areas a higher amount was present. They also emphasized the point, worth noting in passing, that whereas gasoline itself gave an exhaust the only poisonous constituent of which was carbon monoxide, some motor fuels containing a high content of benzene and other related substances, produced toxic gases which were among the most harmful of vapours, causing a progressive and cumulative effect. They drew attention to the fact that the exhaust from motors was far more toxic than smoke from dwelling or factory chimneys. It seems safe to say, when one considers the increase in the use of automobiles and especially of large trucks and buses which everywhere belch out large amounts of exhaust gas, that the atmospheric content of carbon monoxide in city streets is greater to-day than in 1923. Wilson, Gates, Owen and Dawson⁶ examined the blood of traffic policemen after an ordinary day's work and found that it contained in some instances as high as 30 per cent saturation with carbon monoxide, at which point mild subjective symptoms became apparent. Shumway⁷ reported several cases of illness resulting from more or less constant exposure to exhaust gas under the usual conditions of city life. Safe air in public garages having no artificial means of ventilation was examined by Ciampolini⁸ who found that it contained as high as 0.2 per cent of carbon monoxide. Many workmen showed 10 to 20 per cent saturation of their blood and suffered from signs and symptoms of chronic poisoning, as pallor, nervous and gastric manifestations, and insomnia. Apfelbach⁹ described conditions about blast furnaces, in the illuminating-gas industry, power gas industry,

in the use of ovens, and among firemen and boiler operators. Conditions relative to automobile exhaust have been completely reviewed in a report¹⁰ to the New York Academy of Medicine. Hayhurst¹¹ dealt with poisoning from gas stoves, especially those without flues, and Haldane¹² advised that not more than 20 per cent carbon monoxide be allowed in city gas in order to keep air pollution through small leaks below a dangerous level. The proportion of carbon monoxide¹³ in industrial and domestic gases varies between 4 and 30 per cent, coal gas, 4 to 10 per cent, water gas, 30 per cent, producer gas, 20 to 30 per cent. Sundell¹⁴ stated that more casualties occurred in the few days subsequent to the explosion of military mines than at the time of the explosion, as crevices formed in the earth became filled with gas which gradually seeped into adjacent workings. Rutherford¹⁵ reported a mine explosion in 1916 after which gas issuing from the ground burned with a flame visible at a mile for five hours after the mine had gone up. Armstrong¹⁶ analyzed undiluted smoke from cigars and cigarettes and found that it contained as much as 8 per cent and 1 per cent carbon monoxide respectively. Habitual smokers have shown a blood saturation as high as 6 per cent. In an investigation of the hazards from tobacco smoke, Jones, Yant, and Berger¹⁷ found that after forty to sixty minutes smoking in a closed room of 1,000 cubic feet capacity, the carbon monoxide present was never greater than 0.2 per cent. The smoke was four to six times more concentrated than would be permitted under well ventilated conditions, so that the carbon monoxide would be no higher than on streets with heavy automobile traffic.

The importance of carbon monoxide in modern life is well illustrated by the ventilation problem in the Holland Tubes for automobile traffic under the Hudson river at New York. Were a direct draft used to clear them of gas and render passage safe for the occupants of cars, a current of fresh air having a velocity of 72 miles per hour would be required.

SIGNS, SYMPTOMS AND RESULTS OF CHRONIC POISONING

Many accounts of chronic carbon monoxide poisoning have been written, and those of McGurn^{18, 19} are especially interesting. He described fourteen cases showing the pictures of toxic nerve irritations, combined cerebro-spinal

and peripheral nerve lesions, peripheral neuritis, permanent muscular weakness, cerebro spinal irritations, chronic invalidism, petit mal, high blood pressure and vaso-motor disturbances, convulsions and cateleptoid stupor, insanity, glycosuria and pseudo tabes, and multiple sclerosis. These cases were selected from among intelligent individuals, whose histories and co-operation could be relied upon, whom he was able to study intensively and follow carefully, and in whom he excluded hereditary and acquired disease which might obscure or complicate the diagnosis. He further said, "From these and from many other cases seen by the writer, it is apparent that the amount of gas necessary to produce the most profound nervous disorders is exceedingly small, indeed so small that many men and women of experience and education have been permanently injured, owing to the fact that they have failed to appreciate the grave dangers that always exist when coal gas or illuminating gas is inhaled in quantities sufficient to be detected by the normal sense of smell." Egdahl²⁰ listed the immediate symptoms of chronic poisoning as tingling and twitching of the limbs, irritability, numbness of the various parts of the body, feeling of weight in the chest, rigidity of the fingers and toes, attacks of shivering, extreme thirst, various subjective heart symptoms, distress and pain referred to the heart and respiratory distress, while objectively pallor, loss of flesh, red patches over the cheek bones, shiny glittering eyeballs, enlarged pupils, and irregular pulse were noted. Henderson and his associates²¹ at Yale University, in their extensive study of the physiological action of carbon monoxide, described the early effects as follows, "But of all signs and tests the typical carbon monoxide, or oxygen deficiency, headache proved most definite and reliable. It is a distinctly localized pain, usually frontal, throbbing, intensified by lying down or exertion. It is sometimes accompanied by more or less nausea, readily increased to vomiting. The mind is not clear, except by an effort, and one's surroundings seem a little strange. The temper is easily upset, very much as in alcoholic intoxication, and the judgment is likely to be bad. There are wide variations in the degree of this headache, but in the experiments discussed in this section it was never extreme. On the border line it merged merely into slight lassitude. As a criterion of the effect of carbon monoxide,

however, it is more distinct than any artificial test. Concentrations of gas too weak and periods of exposure too short to induce this sign in anyone may be considered entirely harmless." Luden²² reported an interesting personal experience with the gas in her home, and referred to its peculiar action in adhering to objects as garments, rugs, bedding and furniture for lengths of time. The situation pertaining to poisoning in industry has been dealt with by Maver²³ and by Hayhurst²⁴. A consideration of what effect it may have on the not fully developed and growing tissue of infants and children would appear to be important,²⁵ as it is generally conceded that they are affected more rapidly than adults. On the other hand, McCombs²⁶ analyzed 1,000 cases of acute gassing but did not observe chronic sequelæ. Most other writers have laid particular emphasis on the occurrence of such sequelæ.

A finding of diagnostic importance is a rise in the number of red blood cells and in the amount of hæmoglobin, a compensatory mechanism to make up for the cells lost to the circulation through combination of their hæmoglobin with carbon monoxide. Karasek²⁷ examined the blood of operators in iron mills who were exposed to it but who did not show symptoms. Their blood showed a polycythæmia of 5,550,000 to 9,676,000 with hæmoglobin of 95 to 125 per cent, but with no morphological changes in the cells. Nasmith and Graham,²⁸ in an experimental study in which guinea pigs were exposed constantly to an atmosphere of carbon monoxide sufficient to maintain a blood saturation of 25 per cent, found a definite rise in the number of red cells and in the amount of hæmoglobin.

It is true that considerable tolerance to the effects of exposure is developed on the part of some individuals, and also that an amount sufficient to adversely affect some persons shows little or no effect on others. The effects vary in different individuals, suggesting a varying resistance of different parts of the body. In the literature²⁹ to ⁴⁴ one finds many reports of cases of chronic carbon monoxide poisoning, showing a great variety of signs and symptoms. The protean manifestations of its action make it one of the most diversified of diseases.

PATHOLOGY

The pathological findings in patients dying of or a short time after acute poisoning are, as

reported by Stewart³⁵ and by Hill and Semarak,⁴¹ of the nature of degenerative changes in the central nervous system and peripheral nerves. Stewart reported the histological examination of sections of brain, spinal cord, and peripheral nerves in a patient who died twenty-four days after gassing. He found intense universal involvement, bilateral softening in the basal ganglia, and a widespread cortical softening confined to the deeper layers of the grey matter, and concluded that the brunt of the damage fell on the central nervous system. Hill and Semarak in a series of cases found a bilateral ischaemic necrosis of the lentiform nucleus to be a characteristic lesion and felt that carbon monoxide poisoning might be the cause of subsequent nervous and mental disease. They also concluded from the histological appearance of the capillaries that the endothelium was extremely vulnerable. The pathological changes in chronic poisoning are likely similar to these but varying in degree of damage. The diffuse and varied involvement of the nervous system makes understandable the bizarre conditions observed clinically.

ACTION OF CARBON MONOXIDE

The manner in which carbon monoxide acts has been the subject of many investigations. Haldane,⁴² in 1895, in his classical paper "The action of carbonic oxide in man," stated that "the symptoms are due solely to deficiency in the oxygen percentage of the blood and are similar to those experienced by mountaineers and balloonists at high altitudes." Many writers have felt that there is a direct toxic action on tissue, but among physiologists the view of Haldane is generally accepted. The poisonous action of carbon monoxide is due to the fact that the gas combines with haemoglobin, replacing oxygen. If completely saturated the blood would hold the same amount of this gas as oxygen, that is 600 cc. Thus the blood is prevented from carrying the normal amount of oxygen and the animal dies, if the process has gone far enough, from want of it, or if death does not take place serious damage may be done to the tissues of the nervous system from the anoxemia induced. The symptoms of poisoning do not become appreciable during rest until the blood is about one-third saturated. An individual in this condition suffers from palpitation and throbbing of the head and is liable to

become dizzy or faint on any exertion, such as that of ascending stairs, or on sudden exposure to fresh air.

Carbon monoxide has an affinity for the haemoglobin of human blood about three hundred times greater than that of oxygen, and so readily displaces it. The reaction takes place according to gas laws and there is a definite relation between the proportion of carbon monoxide in the air and the extent to which it combines with the haemoglobin of the blood of an individual which has been sufficiently long in such an atmosphere to allow the maximum blood saturation to occur. Many hours of exposure are required to produce this effect. In the typical case of poisoning, the time during which the patient is exposed to the action of the gas is usually not long as in accidental gassing in factories in passage through gas-laden areas and in industrial accidents, and so these figures are not very applicable. Henderson and his co-workers⁴³ have shown that half the maximum saturation possible in a given atmosphere occurs, it is estimated, about one hour's time, and these figures may be practically applied to problems of poisoning. The safe limit of contamination of air for a period of exposure of one hour or less has been fixed by him at four parts carbon monoxide or 10 000 parts of air, giving a blood saturation of 16 per cent in 50 minutes the same could be reached with one part in 10 000 in many hours. This limit is considered safe for invalids and children as well as for robust adults. Such a standard is much higher than that advised by Haldane for the London tunnels, one part in 10 000 but as Henderson points out, the latter was for periods of much longer exposure so that the two standards are in virtual agreement.

Rules arrived at by Henderson and his co-workers⁴³ which may be applied to given situations are: When the time in hours multiplied by the concentration of carbon monoxide in parts per 10 000 equals 3 there is no perceptible physiological effect. When it equals 6 there is just a perceptible effect. When it equals 9 headaches and nausea are induced. When it equals 15 or more the conditions are dangerous to life. If the volume of breathing is increased by exercise (even by slow walking and correspondingly more by physical work) the rate of absorption of carbon monoxide is increased proportionally. After return to fresh air the

elimination of carbon monoxide through the lungs proceeds at a rate of 30 to 60 per cent reduction of the blood saturation per hour." It is seen that the gas has a cumulative action, a prolonged exposure to a low concentration having essentially the same effect as a short exposure to a high one. This is to be distinguished from the cumulative effect seen in chronic poisoning, which is rather the result of anoxæmia caused by frequently repeated gassing. The gas itself remains in the blood only a short time after the subject returns to fresh air. Sayers, Meriwether, and Yant⁴⁸ also studied the effect of exposure to low concentrations, and concluded that the rate of combination, while slow when the subject is at rest, was more rapid when active, that the rate of combination took place much more rapidly during the first hour of exposure than subsequently, and that high temperature and humidity caused more rapid union.

DIRECT TOXIC EFFECT OF CARBON MONOXIDE

Evidence has been brought to show that carbon monoxide under experimental conditions, may have a direct toxic effect on tissue. J. S. Haldane⁴⁹ proved that mammals could live on oxygen dissolved in their blood under high pressure, when almost all their hæmoglobin was combined with carbon monoxide. J. B. S. Haldane⁵⁰ caused death in rats under similar circumstances, by adding more carbon monoxide, showing that direct poisoning of tissue could occur, as the animals already had their hæmoglobin saturated and were living on oxygen dissolved in the plasma. Similar conditions do not, however, obtain in everyday life. Haggard⁵¹ studied the growth of neuroblasts in the presence of carbon monoxide, and found that even in a concentration of 79 per cent no ill effects were observed in the growing nerve cells. In this respect the gas was as neutral as nitrogen. He concluded that carbon monoxide had no specific reaction with nerve tissue, but acted in the body only through the asphyxia, incident to its combination with hæmoglobin. O'Brien and Parker⁵² determined its solubility in serum and plasma and concluded that the amount dissolved in cases of poisoning under ordinary conditions was so small that no allowance need be made for it. Stadie and Martin⁵³ showed that the presence of carbon monoxide altered the oxygen dissociation curve of hæmoglobin and lowered the partial pressure of oxygen in the capillaries, thus de-

pressing the rate of its diffusion to the tissues. The anoxæmia is, then, not entirely due to a reduction of the oxygen of the blood, but also to a lessening of availability of that oxygen which is present. In this way a person whose blood might be half saturated with carbon monoxide would be in a very serious condition, whereas one who had half the usual amount of hæmoglobin as a result of anæmia or hæmorrhage would be in comparative safety. An individual having 15 or 20 per cent of his hæmoglobin saturated, a deficiency which, under ordinary circumstances, would be little noticed, suffers from a much greater degree of anoxæmia. Nasmith and Graham²⁸ exposed guinea pigs continuously for fifteen months in an atmosphere of carbon monoxide sufficient to cause a 25 per cent saturation of their blood. They said "Of the twelve guinea pigs originally placed in the gas chamber fifteen months ago, one died of old age after two months confinement, four died at one time through the carelessness of the attendant, one after seven months was transferred to fresh air again, and five have been killed for pathological study. None of the animals decreased in weight, on the contrary most of them gained. After the first few days, those living with 25 per cent of their hæmoglobin saturated with carbon monoxide appeared just as active and happy as those living in the air." It would seem from this that the gas is innocuous as far as guinea pigs are concerned, and these results probably indicate that small animals are not suitable for the investigation of chronic poisoning as seen in man. Zeigler⁵⁴ produced late mental and nervous symptoms in dogs by gassing them with illuminating gas. In all likelihood the nervous constitution of an animal determines the effect of carbon monoxide upon it, the higher being more susceptible than the lower. On the whole, there is little evidence that carbon monoxide exerts a direct toxic effect on nervous tissue under clinical conditions.

The term carbon monoxide is loosely used in the literature, except by laboratory workers. It is assumed to be the poisonous agent in various mixtures of gases. While it is certainly the main one, it may not be the only one. Haggard⁵¹ showed that pure carbon monoxide had no effect on neuroblastic cultures, but he also showed that illuminating gas was toxic for them in concentration even as low as 0.1 per cent, and concluded that it contained another toxic substance.

The toxicity of pure carbon monoxide, illuminating gas, exhaust gas from gasoline and exhaust gas from coal distillate, has been compared by Henderson and his associates²¹ by gassing dogs to the point of death and examining the blood. With pure carbon monoxide, an average of 84 per cent blood saturation was found, with illuminating gas an average of 70 per cent, accompanied by nausea and vomiting which were lacking in the experiments with the pure gas, with gasoline exhaust, an average of 83 per cent, much similar to pure gas, and with coal distillate, an average of 62 per cent, nausea and vomiting more severe than with illuminating gas, and in addition a brownish tinge to the blood indicating a destructive influence on the hæmoglobin. Hamilton²² referred to loss of consciousness in benzol poisoning with two or three parts of benzol in 100,000 parts of air, and in one instance death from typical benzol poisoning from exposure to one part in 10,000. It would seem quite probable that some of the effects of gas poisoning may be due to minute quantities of substances other than carbon monoxide, although without doubt the major effect is due to it.

PREVENTION

Since treatment is of little avail after the damage caused by chronic poisoning is done, the approach to the problem lies entirely in prevention. This consists in reducing in all ways possible our contact with the gas. In industry much is being done to protect workmen, but it is unlikely that anything will be done to protect the general public from such an ubiquitous source of carbon monoxide as the gasoline engine until an enlightened public opinion demands it. A vertical exhaust, as a remedy, has been tested and proposed by Henderson and Haggard⁵. The heated gases, thrust upward escape into the air above the street and are rapidly carried away, but when expelled along the ground are chilled by the cold surface, mixed with the air by other vehicles, and lie in a poisonous layer at respiratory level. We cannot allow furnace smoke to escape at street level. Why should we permit automobile exhaust gas to do so, especially when it is so much more dangerous than smoke from chimneys? In round-houses each locomotive has a chimney through which smoke escapes. It would seem possible for every garage to have an outlet in

the roof through which exhaust gas thrown upward from a vertical pipe would escape to the outer air and so reduce the increasing death rate from accidental asphyxiation. It is not likely that motor car manufacturers of themselves will alter the design of cars to meet this problem.

Much carbon monoxide escapes into homes from leaky illuminating gas pipes and fixtures, and from poorly adjusted gas stoves, and is breathed by the occupants for long periods of time without the realization that it is present. Especially is this so when the sense of smell is not acute, as is the case with many people. Were careful inspection for leaking gas instituted as is made for uninsulated electric wiring, much of this would be eliminated. But the danger of fire from small quantities of gas being negligible, the incentive for inspection is lacking and will not be supplied until a realization of the health menace from carbon monoxide makes it imperative.

There seems little reason for the extreme anxiety shown by some writers, lest the production and accumulation of carbon monoxide seriously handicap or endanger our present civilization. A writer in *Science*⁶ said, "There is probably more carbon monoxide produced during a severe lightning storm in a given locality than is emitted by our coke burners, gas engines and other sources in industry during much longer periods." Serious as is the problem and beset with difficulties not often encountered in public health work, there would appear to be no reason why it should not be met successfully.

DERMATITIS VENENATA*

W R JAFFREY, M B

Hamilton

DERMATITIS venenata is a very large subject. Newer work on the problem is clearing up the field, and the purpose of this paper is to offer and discuss a few examples of the dermatoses caused by external irritants. Emphasis will be placed on those coming under the classification of occupational or industrial, as these are the most important, economically, to the worker, and unless they are studied carefully, we cannot expect to get proper recognition from the employer or the compensation board. In England these cases are carefully investigated by the compensation authorities. Some states in the American Union do this also, while others depend on insurance companies, but in Ontario there is no adequate clause covering these cases, unless a definite injury precedes the attack, and then it is classed as an injury. Therefore, a very careful history must be taken of the patient's past, as well as present, environment that the case may be properly presented if necessity arises. Although the treatment of the patient seems most important, yet the hy-

gienic and prophylactic aspect of the case should be carefully explained to him, thus teaching him how best to avoid future attacks. Many of these patients have had recurrences, have been told that it was their blood, and are hard to persuade that blood medicine is unnecessary.

Going over my statistics roughly, I would estimate that about 20 per cent of cases seen in my practice are dermatitis, and fully 75 per cent of these would come under this grouping, either directly or indirectly, therefore an insight into the "why" is all important. R P White says, "As etiology disentangles the causal from the casual, we realize that there are comparatively few idiopathic or primary eczemas," and if the name of the offending irritant cannot be given, the terms "traumatic," "occupational," or "professional" should be prefixed. The all important point to remember is that in every occupation the worker is exposed to irritants, and every irritant can cause a dermatitis in a susceptible skin. This depends on the sensitivity of the individual epidermis or tissues exposed, and such a sensitivity can be acquired, similarly to that of horse serum and other proteins, by con-

SOME OBSERVATIONS ON THE EFFECT OF BLUEBERRY LEAF EXTRACT IN DIABETES MELLITUS

By E. M. WARREN

*Department of Medicine, University of Western Ontario Medical School,
London*

REFERENCES to various so-called insulin substitutes have appeared in recent medical literature. The term 'insulin substitute' is perhaps an unhappy one. To those familiar with the beneficial effects of insulin in diabetes, the search for a substitute for this potent remedial agent may seem unwarranted. The efficacy of insulin in the treatment of diabetes mellitus is indisputable. Its mode of administration, however, bears disfavor. No method of administering insulin has yet been successful except by subcutaneous injection. Hypodermic medication, continued day after day, with unmitigating care and precision is objectionable for very obvious reasons. Moreover, insulin is a powerful drug which, if misused in the hands of patients, possesses potentialities of due consequence. Hence, hope ever exists that some substance may be prepared which when taken orally is capable of exhibiting the desirable properties of insulin, but is devoid of its disadvantages. Such an ideal therapeutic agent is not yet available.

The amount of insulin absorbed from the gastro-intestinal tract has generally been considered too insignificant to be of any real value in the treatment of diabetes. However, the observations of Murlin and Hawley¹ suggest that pancreatic hormone replacement by this route may not be an impossibility.

In the absence of an insulin-containing product which is efficient when taken by mouth, it may not be amiss to investigate certain non-pancreatic preparations from the standpoint of a possible salutary influence upon the carbohydrate tolerance of diabetic patients. Remedies of this class which have received attention recently are synthalin and blueberry leaf extract. Synthalin, although it appears to offer certain possibilities, is apt to give rise to unpleasant toxic by-effects. Blueberry leaf extract seems to be harmless, but its proper evaluation as a factor in the treatment of diabetes has not yet been decided. The following data have a bearing upon this latter consideration.

PREVIOUS OBSERVATIONS

Experimental evidence points to the existence in many or all plants of a substance which affects carbohydrate metabolism.^{2,3,4} The leaves of the blueberry plant are said to contain this ingredient in relative abundance, in a form which permits of extraction.

The physiological action of an extract prepared from blueberry leaves was first investigated by Mark and Wagner.⁵ This investigation was soon followed by observations relative to its effect in depancreatized dogs.⁶ The variable results obtained by these workers were explained by the demonstration of two antagonistic principles in their preparations. The one tended to raise the blood sugar, the other to lower it. An attempt was made to separate and purify the latter substance, and the resulting product was given the name myrtillin.

On this continent, the problem has been investigated chiefly by F. M. Allen,⁷ who believes "that myrtillin plays some accessory part in carbohydrate metabolism and that, if properly used, it will prove valuable as an accessory factor in diabetic treatment." This contention was the outcome of experimental observations in totally and partially depancreatized dogs and in clinical cases of diabetes. The lives of depancreatized dogs were prolonged by the use of myrtillin. Fluctuations in the blood sugar under similar conditions were apparently not so marked, and the amount of insulin required by the animals was probably less than when no blueberry leaf extract was used. Even the largest doses were without evident toxic effects.

Allen was able to report on eighty-one cases of diabetes treated with the drug. In sixty of these, conditions were such as to permit of comparative studies. Beneficial results, attributable apparently to blueberry leaf extract, were believed to have been obtained in thirty-six cases of this latter group, as evidenced by their ability to tolerate a higher daily consumption of carbohydrate, to decrease the amount of insulin, or

TABLE I
SUMMARY OF CASES TREATED WITH BLUEBERRY LEAF EXTRACT

both In general, the best results were obtained in the milder cases and in middle-aged or elderly patients Myrtillin never caused hypoglycæmia, but rather tended to prevent hypoglycæmic reactions due to insulin The beneficial effects, when obtained, were indefinite in duration, and seemed to be prolonged, after stoppage of the remedy, for from one to several weeks This phenomenon was explained on the assumption of storage within the body The mode of action of myrtillin in bringing about improvement in carbohydrate tolerance is unknown It has been suggested that the active principle may be of the nature of a vitamine In this regard, it is noteworthy that Mills⁴ has recently obtained encouraging results in the treatment of diabetes with a vitamine-rich extract of various plants administered by mouth His preparation, however, was without effect in depancreatized dogs, but it increased glycogen storage in the livers of rabbits kept on a constant diet

FURTHER DATA

There are recorded here the results of the administration of blueberry leaf extract to sixteen patients with diabetes mellitus of varying grades of severity and varying lengths of duration The extract was supplied in the form of tablets, 0.3 grm each, one tablet being given one hour before meals The results are summarized in Table I The blood sugar estimations were carried out by the Folin-Wu method, upon blood samples obtained during the morning fasting state, unless otherwise designated Apparently beneficial effects were obtained in nine cases (56 per cent) As noted above, Allen claimed beneficial effects in 60 per cent of a larger series of cases

In Table I, the insulin dosage before the exhibition of blueberry leaf extract refers to the amount of insulin received by these patients immediately before blueberry leaf extract was started, not the maximum requirements of the

individuals previous to this time. The insulin dosage after blueberry leaf extract indicates the minimum amount of insulin needed after the use of the tablets. For example, the case record epitomized in Table II shows that an attempt was made to reduce the daily requirement of insulin to a minimum while maintaining the urine aglycosuric and the fasting blood sugar normal, first without blueberry leaf extract, and afterwards with blueberry leaf extract. This patient, on admission to hospital, presented the manifestations of moderately severe diabetes. The diet and insulin were as indicated. The insulin was gradually reduced, from a maximum of forty-five units per day on a constant diet to twenty units without glycosuria and without elevation of the fasting blood sugar. But when the insulin was further reduced to ten units per day, glycosuria appeared and the blood sugar rose above the normal. The patient was again

given twenty units of insulin a day, and blueberry leaf extract was started. After about one week, reduction of the insulin was once more attempted. The insulin could now be eliminated entirely, the urine still keeping sugar-free and the blood sugar normal.

Considerable variations in effect were encountered in different patients and in the same patient at different times. Such discrepancies were referable, perhaps, to variations in potency of several lots of tablets or to vagaries in absorption. The effects of the remedy were lost in the presence of even a slight infection (Table III). Ketosis was not readily corrected by the drug (Table IV). As regards the inhibiting effect of blueberry leaf extract upon hypoglycæmic reactions, it may be said that blood sugar concentrations as low as 0.047 per cent have been observed during the period of its administration, without the usual manifestations of insulin shock.

But reactions have not been absent. The effects could not be appreciably augmented by giving double the usual dose.

DISCUSSION

The above results, based upon purely clinical observations, would seem to support Allen's view that blueberry leaf extract has a stabilizing influence upon the carbohydrate tolerance of certain cases of diabetes. That it cannot take the place of insulin need not be gainsaid. But, if it can be shown to permit the dosage or frequency of administration of insulin to be decreased, or cause insulin to be eliminated entirely in certain cases, or allow for added carbohydrate intake without increasing insulin, its use is justified. Judgment regarding the value of a therapeutic agent of this sort is truly difficult and one must weigh the evidence carefully before arriving at conclusions. The fallacy of basing opinions upon a small number of observations is also realized. As everyone familiar with the malady knows, the course of diabetes is variable. There exist all grades of severity between the case which can be readily controlled by minor dietary restrictions and that which cannot be balanced even with large doses of insulin. That carbohydrate tolerance does improve as a result of, or in spite of, insulin is common experience. An example is shown in Table V, in which the daily amount of insulin was reduced from fifty-five

units to zero in the course of about eight weeks. Had any treatment been employed other than that which was used in this case, one might have been led to quite erroneous deductions.

Tangible evidence in favour of the regeneration of pancreatic islet tissue as a result of insulin has been furnished by Boyd and Robinson.⁸ It is also true that the daily insulin requirements of many patients remain unaltered or even need to be increased. Such cases have been reported by Newburgh,⁹ Harrison¹⁰ and Brace.¹¹ Efficient diabetic therapy is a composite process to which many factors contribute. Whereas insulin acts as a specific under certain conditions, the mainstay of diabetic treatment still lies in the realm of dietary regulation. The importance of under-nutrition has been emphasized by Rabinowitch.¹² Other factors which are known to influence carbohydrate metabolism in the diabetic, such as muscular exercise, infections, an altered basal metabolism, and time should be given their proper due in any individual case.

Therefore, one may justly ask the following questions: Was the association of blueberry leaf extract administration and improvement in carbohydrate tolerance in the cases above mentioned merely a matter of chance? Could the recuperation of the metabolic functions be accounted for by one or several of the factors to which reference has just been made? Were these patients, at the time the blueberry leaf

was started, receiving more insulin than their required minimum? These are, of course, all possibilities. The only reply to such speculations is that in several instances unsuccessful attempts at insulin reduction or dietary increment had been made before blueberry leaf extract was given, also, there were indications in certain cases of a decline in carbohydrate tolerance when the extract was withdrawn.

If a preparation, such as that under consideration, possessing possible insulin-like properties, is to be available for general use, some means of standardization is necessary. To date, a satisfactory method for this purpose does not seem to have been evolved, hence, a uniformly potent product can not be assured.

SUMMARY AND CONCLUSIONS

A limited experience with the use of blueberry leaf extract in the treatment of diabetes mellitus permits the following generalizations, in which the claims of Allen have been at least partially verified.

1 Blueberry leaf extract appears to exert a beneficial effect in certain cases of diabetes. Its action is not consistent.

2 Its utility is most apparent in middle-aged or elderly patients, and in mild cases of the disease.

3 Owing to its relatively slow and feeble action, the drug is of no avail in the emergencies or complications attendant upon diabetes.

4 Blueberry leaf extract can not be regarded as a substitute for insulin, generally, but it may become an adjunct in the treatment of diabetes.

5 Blueberry leaf extract is without evident deleterious effects. It does not give rise to serious hypoglycæmia.

6 Withdrawal of the drug may be accompanied by a partial relapse in carbohydrate tolerance after a variable length of time.

7 Finally blueberry leaf extract has, at best, a limited application in the treatment of diabetes, and exaggerated confidence in any therapeutic agent is to be deprecated.

An Address

ON

ASTHMA*

By DANIEL NICHOLSON, M.D., M.R.C.P. (LOND.),

Faculty of Medicine, University of Manitoba

Winnipeg

ASTHMA is a constitutional disease with an hereditary tendency. That it is constitutional is shown by the manner in which it may recur after an absence of several decades. The hereditary factor is also well established. It is as fitting to speak of an asthmatic constitution as it is to speak of a melancholic disposition. If one regards the asthmatic as one who is capable of having asthma it is hardly an exaggeration to say "Once an asthmatic, always an asthmatic."

Since Sir John Flower published his classical

treatise in 1698, proof of the muscles of the smaller bronchi has been taken as the cause. Kessler recently did experiments to substantiate this, but other investigators state that the cause is not so certain and that probably action of the epithelial cells lining the bronchi produces the narrowing. I have tried to demonstrate spasm by means of lipiodol injections into the lung but have not been successful. There was no apparent difference in the width of the shadow during an attack compared with its width during the freedom from asthma experienced after injection of adrenalin. Cocainization of the throat for

*Read at the Annual Meeting of the Canadian Medical Association, Charlottetown, June, 1928.

lipiodol instillation will in itself usually relieve the attacks and it is difficult to keep much lipiodol in the bronchus on account of the irritable cough most asthmatic patients have. I have made a direct observation of the bronchial mucosa through a bronchoscope at Dr Haslinger's clinic in Vienna. The bronchi are filled with tenacious bubbling mucus and the lumina of the larger visible bronchi narrowed only in the same degree as when a patient not subject to asthma coughs. The mucosa has exactly the same appearance as the nasal mucosa in hay-fever. The membrane is of a deep red colour, with a few paler mottled areas. It is definitely swollen and a probe sinks into it more deeply than in the normal. It is normal between the attacks. Postmortem studies of patients who have died from acute asthma confirm this. The cilia are absent from the epithelial cells and the submucosa is very oedematous. The heart is normal. The evidence is more definite that this vasomotor swelling of the epithelial and subepithelial tissues, together with the increased viscid secretion from the mucous glands, is a cause of bronchial narrowing rather than muscular spasm of the bronchioles.

While we are very familiar with many of the external phenomena of asthma, we do not know either its true nature or its fundamental cause. Research here may some day open up to us better means of treatment, but for the present, the management of the disease is of more immediate importance. I must here confess that I have not been able to duplicate the good results published in many of the journals and recent text-books no medicine. One of the most difficult of problems is to establish a therapeutic fact in the case of a non-fatal disease. A glance at the pages of medical history shows us how frequently even the great masters in medicine saw the results they wished to see following some method of treatment which we know now could have had no effect whatever on the course of the disease. One thing is certain, in speaking of the result of treatment in asthma we should banish the word "cure" and speak of "freedom from symptoms," for one year or five year periods, and with this we should be ever mindful that asthma is a disease in which the most unexpected remissions occur spontaneously, especially in the young.

As asthma varies enormously in its severity and persistence, a classification may help. From the standpoint of management a classification according to age is probably the most useful. The first group comprises babies up to three years

of age, the second group, from three to thirty-five years, and the third group over thirty-five.

These types of asthma and their necessary investigation can be best illustrated by typical cases.

CASE 1

D. A. a baby three weeks old developed in September 1922, a generalized, weeping eczema. His family history showed some member to have had asthma or hay fever for the past five generations. He gave positive cutaneous reactions to egg and both human and cow's milk. As restricting the mother's diet in the matter of eggs and cow's milk did not help him, he was weaned and put on dried milk. With this he showed an appreciable improvement, but a definite eczema remained. Ointment made up of 25 per cent tar produced a good result, so that during the following summer only a few eczematous areas remained on the hands and face. In November, 1923, he developed bronchitis and asthma. Cutaneous protein reactions at this time were still positive to egg, but negative to milk. He now showed additional reactions to rabbit hair and duck feathers. Rabbit hair is frequently used in mattresses but placing him in a special room away from contact with hairs and feathers produced no change. We expected that it would. A course of protein desensitization gave relief in about six weeks. He had only very slight attacks until 1925, and his mother then noticed that bananas were a cause of his attacks. Although he still showed a slight cutaneous reaction to duck feathers and rabbit hair he showed no reaction to banana protein. The mother then gave a small amount of banana on two occasions and asthmatic attacks followed each feeding. He had attacks apart from taking bananas, however. After a further course of desensitization with rabbit hair and duck feathers and by avoiding bananas, he has remained well until the present.

Tonsillectomy and adenoidectomy do not seem to help such cases. For one that is improved another is made worse. Ephedrine, in quarter grain doses, usually gives satisfactory relief for six hours, but it causes constipation. Tar ointment is a valuable adjunct in the treatment of eczema. The administration of cod liver oil or one of the vitamin D concentrates is a useful prophylaxis for the bronchitis which aggravates the asthma.

CUTANEOUS REACTIONS TO PROTEINS

The protein reactions may be discussed here. The procedure is simple and requires about an hour. Keep the groups of the protein vials in envelopes labelled "vegetables," "meats," "milk," and "eggs," etc. Make a series of small scratches on the arm of an adult or the back of an infant so as barely to draw blood. Place a small drop of one-tenth normal solution of sodium hydroxide beside each scratch. Take, on the end of a toothpick, a small amount of powdered protein from the vial and place it in the scratch, rubbing in the sodium hydroxide to dissolve the protein. Place in a row the vials from which the proteins have been removed separating each group, such as vegetables, meats, etc., with a toothpick.

Make a penmark at the end of the corresponding group of inoculated scratches on the arm. In this manner one can locate the protein causing the reaction. The reactions occur in five to ten minutes as white raised wheals surrounded by a red blush. It is well to note the size of the wheal. The larger it is, the more definitely is the cause established.

The list of proteins need not be large. If one employs more than one hundred in a large series of cases, eighty per cent of the reactions will be given by less than two dozen of our commoner foods and hair or feather dusts. The most important foods are eggs, milk, and wheat. These three foods give more reactions than all other foods. Of the animal emanations, horse, dog, cat or rabbit hair, and feathers of the chicken, duck and goose, are the main offenders. The pollens vary according to the locality. June grass, timothy, and ragweed are the most troublesome. Practitioners will find the following list of thirty valuable—whole egg, cow's milk, wheat, oats, potato, cabbage, lettuce, beans, tomato, orange, peanut, beef, mutton, chicken, salmon, herring, codfish, cocoa, horse, dog, cat and rabbit hair, chicken, duck and goose feathers, ornitho root, June grass, timothy, ragweed low and tall, with sagebrush added for the western provinces.

If one wishes to employ a very complete list he may add the following forty-seven to the above list—sub-proteins of egg, ovomucoid, ovo-vitelline, egg white, egg yolk, sub-proteins of cow's milk, casein, lactalbumen, peptone, and proteose, sub-proteins of wheat, leucosin, gliadin, glutenin, globulin, and proteose, beet, tea, celery, cauliflower, rice, veal, pork, white-fish, lobster, apple, banana, pear, walnut, paprika, mustard, mayonnaise, cow hair, muskrat, fox, cottonseed, flax, sheep's wool, glue, tobacco. Pollens will vary according to locality, but the most frequent reactions will occur with willow, maple, red top, orchard grass, rye grass, dandelion, marsh elder, cocklebur and wormwood. When using a very extensive list of 275, less than one per cent of the reactions of any importance will occur outside of the above list.

If a patient complains that house dust will cause attacks, enough of the floor sweepings to fill a thimble may be dissolved in twice its volume of one-tenth normal sodium hydroxide, and after allowing several hours to effect solution, shaking, and then centrifuging, the supernatant fluid may be applied to a scratch. If a reaction occurs and it is impossible by means of vacuum cleaners,

etc., to keep the patient away from house dust, any biological laboratory will prepare suitable sterile extracts for treatment from a sample of the dust.

From the standpoint of diagnosis and treatment cutaneous protein tests are useful in children and young adults. They rarely give information in patients past middle life and autogenous vaccines should be the mainstay of treatment. In the past, many attacks of asthma in babies were diagnosed as croup and bronchitis. Where asthma is present there is frequently a concomitant eczema. These conditions, while fundamentally inborn, are very much aggravated by certain proteins, principally those in the food, though house dust may at times be a cause.

If a nursing baby be sensitive to a protein such as egg-white, its asthma will be aggravated by eggs in the diet of the mother. Although infants suffering from eczema and asthma usually show cutaneous reactions to egg and milk and other food proteins, they do not always improve when their diet is adjusted to avoid the substances. In these who are hypersensitive to foodstuffs, the reactions to hair and feathers frequently develop later. The many very strong reactions to horse hair are difficult to explain from the standpoint of previous exposure to that substance. Only three out of four babies will show any reaction to an extensive list of more than one hundred proteins. Hypersensitiveness to proteins and the cutaneous reactions frequently disappears spontaneously at about the age of three years. The reactions sometimes vary from month to month. Among those who show reactions, an acute bronchitis, such as occurs in the winter months, frequently initiates the attacks.

Protein reactions in infants may frequently be determined by a careful history. A child usually vomits shortly after taking food to which it is very hypersensitive, or it may break out in a rash twenty-four hours after taking such a food. However, where small amounts are taken, or where the food is a daily one, such as bread and milk, and the parents not very observant, it is well to test for and exclude from the diet all food to which the child is hypersensitive, and to keep it from contact with hairs, feathers or dusts which give reactions.

Do not think that protein-sensitization, diagnosis and treatment are the beginning and the end in the management of asthma. This phenomenon has been investigated by modern methods only within the last ten to fifteen years. It is, there-

fore, relatively new. As with everything new, the reports of results have been too optimistic. The protein-sensitization test has, however, established a definite place for itself in the diagnosis of asthma. It may be used to confirm the truth of the statement from a patient that eating a certain food, or contact with a certain dust, will produce an attack. More frequently, substances that the patient did not suspect will be demonstrated as an exciting cause. The effect may be proved by actual contact later.

The following is a case in which cutaneous reactions and desensitization proved valuable.

CASE 2

H. R., a female, 29 years old, referred by Dr. F. A. Benner, had had asthma for the past twenty years. Until the age of eighteen years she had lived at Maple Creek, Sask., a settlement with a high and dry location. After that she lived for ten years in Edmonton, and had been in Winnipeg less than a year. She was almost a chronic invalid, having very severe asthmatic attacks daily, and only through remarkable will power and four or five daily hypodermic injections of adrenalin was she able to continue her work as a stenographer. Having an acute perception, she was able to state definitely that horses, dogs and cats make her break out in nettle stings and make her asthma worse. Sagebrush which pollinates in the fall, would also aggravate it. She was given a course of desensitization to horse and dog hair for over four months. She did not improve for the first two months, but after that the attacks became less severe, until by the end of the treatment she was almost entirely free from symptoms. Only by a brisk walk against a cold wind could she start up a wheeze. After six months she began

to notice a slight return of the asthma on hot days. The protein tests now showed the reactions shown in Fig. 1. They were twice this size before the course in desensitization. On account of the horsehair reaction now being so much larger than the others it was used in combination with sagebrush pollen for a second course in desensitization. This should give an added period of freedom from asthma, but it is impossible to forecast whether or not this patient will be free from asthma in old age.

DESENSITIZATION

Before undertaking a course in desensitization every effort should be made to keep the patient away from food or substances which cause his symptoms. The physician should give the patient explicit instructions and, if this does not result favourably, he should visit the patient's home in the rôle of a Sherlock Holmes to ferret out materials which might be a cause. If this is successful, even occasionally, it repays many unfruitful efforts. Desensitization is time consuming, it is not a pleasant procedure for the patient, and it involves considerable expense. However, desensitization may be the only way out, as when the offending substance is ubiquitous and likely to meet the patient in many places he cannot avoid. It is justifiable to desensitize a farmer to horsehair emanations if he cannot engage in any other occupation. The aim in desensitization is to establish a tolerance by means of gradually increasing doses of a substance to which the patient is hypersensitive. In patients who are markedly hypersensitive, especially to the animal emanations, desensitization is very slow and never complete. A partial desensitization, however, will permit a patient to come in contact with small amounts of the offending substance, without developing symptoms. If hypersensitive to horses such a patient may drive behind them, though he cannot groom them. A year after desensitizing some tend to become as hypersensitive as they were originally. The patients with large reactions manifest the best results from desensitization. Patients who show wheals less than an eighth of an inch in diameter frequently do not benefit from such treatment. From multiple reactions the largest of each group should be combined for desensitization treatment. The directions given by the biological houses with desensitizing protein solutions are satisfactory, but it is frequently necessary to continue for some time with larger doses than advised of the stronger solutions, in order that sufficient tolerance may be developed. One minum of a 1-10,000 solution of the protein is the usual dose with which to commence treatment, but it is best to put a drop of the 1-10,000 solution in a scratch, and, if the

FIG. 1.—Cutaneous protein reactions following four months of desensitization in patient No. 2. They were twice this size before the course of injections.

wheal is more than $\frac{1}{8}$ inch wide, to give one tenth of the dose by diluting the 1-10,000 solution

For the first half dozen doses, each may be twice the previous one. Later it is best to increase in slower steps by having each dose one and one-half times that of the previous one. *One cardinal principle is that the injections should not be so large that they give the patient asthma.* If the symptoms are worse within six hours after the injection the dose is too large and should be decreased to half the last given and increased at half the rate suggested above. The local reaction should not be over three inches in diameter and it should start to fade in six hours. Walker originally gave injections at weekly intervals, but Duke has recently obtained good results using only a daily interval. Three injections weekly at first and later twice weekly are satisfactory.

The course of injections should be continued for two to three months or until the patient can tolerate one c.c. of a one per cent solution. This may require a long time, especially in a patient who is very sensitive to animal hair. Following this one may continue with monthly injections of the last dose for a period of one year or repeat the course if the symptoms recur, which is frequently the case in a year or two.

We do not know what the remote results of desensitization may be. Only after it has been in use for a lifetime can we determine whether the treatment in childhood tends to prevent asthma in old age.

Drugs do not interfere with desensitization, so that one may give ephedrine or adrenalin for immediate relief. Ephedrine is always worth a trial in a patient who is protein-sensitive. It rarely gives relief to elderly patients who have a continuous type of asthma. It can be taken by mouth and its action is more prolonged but less certain than that of adrenalin.

A change of climate, always an expensive experiment, does not benefit protein-sensitive patients if they are exposed in their new locality to the protein to which they are susceptible. A change of residence to a new house a hundred yards away or to a sparsely furnished hospital room will remove the patient from the source of trouble and often give as much relief as a haphazard journey of a thousand miles.

About 60 per cent of asthmatic patients from 3 to 35 years of age show protein reactions. One can, by a history, frequently distinguish patients who are protein sensitive from those who are not.

Those protein sensitive have little or no purulent bronchitis. They have definite attacks, lasting several hours to several days, and then definite remissions, when they are entirely well. The attacks are usually associated with a definite location or occupation and the onset is characterized by sneezing. The non-sensitive types have a more continuous asthma. The onset is usually from two to five in the morning. Patients hypersensitive to feathers usually develop attacks within an hour after going to bed. The non-sensitive are usually past middle life and are very much worse during an attack of acute bronchitis. Many elderly patients who show no reactions give a very distinct history of being, in their youth, hypersensitive to specific substances such as horsehair.

Out of three patients showing the protein reactions one will obtain no relief from his asthma by abstaining from the substance to which he is hypersensitive or by a course in desensitization. Another will have a stubborn respiratory infection and there is little relief by desensitization. The third will have marked relief by desensitization for a period varying from one to three years and a repeated course of injections will frequently extend this period. This is the type of case that encourages one to do protein tests and desensitization. The patient not showing any definite protein reaction should be treated in the same manner as asthma in the elderly.

Asthma in old age is the least hopeful of all types. It is usually continuous and associated with a bronchitis which is worse in winter. Cardiac, renal and aortic dyspnoea (so-called asthma) should be excluded by careful physical examination.

CASE 3

D. M., 58 years of age, is a good example of this type. He entered the General Hospital, under the care of Dr. E. S. Moorhead, complaining of weakness, asthma, cough and expectoration. This patient had been suffering from asthma for twenty-four years. He came to Canada from Scotland, eighteen years ago in search of health. He has not yet found it. He had had asthmatic attacks two or three times a week during all these years. For the past four years the attacks had been more frequent, until they came on whenever he exerted himself, even moderately. Since 1922 he had frequently coughed up small amounts of blood in the morning, and for the last year his sputum had been more than six ounces daily, of thick yellowish material. He had had considerable pain in his right side, aggravated by coughing and deep inspiration, and had lost so much weight that he appeared to be quite wasted. His chest was prominent with the right shoulder lower than the left. There was considerable bowing of the spine both posteriorly and to the left, and examination of the lungs showed relative dullness due to old tuberculosis in the right apex and marked active pyogenic disease at the base. The bronchus was pulled to the right and lipiodol did not penetrate the base of the lung but floated

ported, the typical Pel-Ebstein type of temperature was the feature that made us strongly suspect the disease. However, in the ambulatory and intermittent types, the Pel-Ebstein type of temperature is not present, there may be only slight fever, or it may be intermittent with varied clinical findings, such as arthritis, neuritis and phlebitis. The diagnosis must, of course, finally rest with either a positive blood culture of the *Brucella abortus* or positive agglutination tests with that organism. Agglutination at high dilutions has been insisted on by many observers in America. However, Sensenich and Giordano believe agglutination in a dilution of 1:50 to be diagnostic.

The cases here reported are of interest because they are among the first fully reported, which have occurred in Canada. Also, one patient (Case 1) had an illness lasting ten months, and was in various hospitals in Canada, and under treatment for various diseases before the true nature of his disease was discovered. Another reason for reporting these cases, with a brief outline of *Brucella abortus* infection in man, is that we believe the infection in Canada to be more common than is suspected. If attention is drawn to the possibilities of the disease, and laboratory facilities are available for the agglutination of the blood, many more cases will be diagnosed.

CASE 1

A man (B. R.), aged 22 years, born in Italy, had been in Canada for one year. He was first seen by one of us (I. S.) on April 22, 1928, when he stated that he had been sick for eight months. There was nothing in his history prior to September, 1927, which appeared relevant. He had had no illnesses while in Italy, and was well for a period of months after coming to Canada.

It was rather difficult to obtain an accurate history but the patient said he had been sick for eight months with a fever, and profuse perspiration, loss of strength, cough with sputum, and slight, vague aches in his joints. During these eight months, from September until April, he had consulted many physicians and had been in one hospital for two months, with a diagnosis of typhoid fever, with four relapses. He had occasional rigors during the eight months. The things which bothered him most were the periods of high temperature associated with very profuse perspiration, some loss of appetite and the pains in his joints. However, he did not consider himself very ill and had been up and around for the greater part of his illness. It was impossible to obtain any further history except that a physician would visit him when he was feeling sick and find a temperature of 104 degrees, upon his return next day he would be surprised to find a normal temperature.

Physical Examination—On April 22, 1928, the patient first presented himself for examination. He was thin, with flushed face and did not appear to be very ill. Temperature 103°, pulse 80. There was diminished resonance at the left apex with increased bronchophony and broncho-vesicular breathing. No rales were heard.

The liver was not enlarged, the spleen appeared to reach one finger's breadth below the costal margin and was not tender. The examination was otherwise entirely negative. There were no glandular enlargements, no petechiae nor rose spots, no apparent disease of the joints or peripheral nerves.

Laboratory Examination—Urine normal. No pus present. Sputum was negative for tubercle bacilli. Blood: white blood cells 6,000 per cmm, red blood cells 3,800,000 per cmm, haemoglobin 80 per cent (Sahli). The smear showed a moderate secondary anemia. Differential count: polymorphonuclears 40 per cent, lymphocytes 54 per cent, monocytes 6 per cent.

X Ray Examination—Fluoroscopic examination was made and showed the mediastinum to be clear. Stereoscopic plates were made of the chest, which showed a minimal parenchymatous tuberculous infiltration at the left apex, with thickening of the ascending bronchus on the right.

A tentative diagnosis of tuberculosis was made but the patient was sent to hospital for observation, as we were unable to ascribe an eight months' illness, with high fever, to such a small area of tuberculous involvement which moreover, showed no signs of activity.

Progress—For the first week of his stay in the hospital the patient showed marked remissions in temperature, from 104 to 99 degrees in an hour. At the time of the drop in temperature, the patient experienced the most profound perspiration. He did not appear to be very ill and complained of nothing but the drenching sweats, slight loss of appetite and cough with sputum.

Physical examination during this week showed no change from the initial examination, except that there appeared a few medium moist rales throughout the lungs. Repeated urinalyses were negative, as also were repeated sputum examinations for tubercle bacilli. White blood counts, taken during this week at various temperature peaks, showed a constant leucopenia, about 6,000, with a relative lymphocytosis. The blood smears were searched for malaria parasites and the spirochetes of relapsing fever, but none were found. The Widal test, by the macroscopic method, showed no agglutination to typhoid or paratyphoid.

May 1st to 14th—The patient remained much the same, except that the temperature did not go so high and there were no marked remissions. The temperature curve did not show any undulating character, however, he had a fever from 100 to 102 degrees every day. A mild phlebitis developed in the right leg, which cleared up in four or five days. Later, he developed a painful swollen elbow, which was not red. The pain and swelling disappeared in about three days.

All attempts to find a cause for his temperature were unsuccessful. Intravenous neosol was given as a therapeutic test for relapsing fever. The arsenic failed to influence the course of the disease, so that we felt safe in ruling out relapsing fever as a possible cause of his illness. There were no signs of activity in the minimal tuberculosis present. A subcutaneous tuberculin injection gave a marked local but gave no systemic or focal reaction.

May 14th to June 1st—About May 14th, we received, through the kindness of the hospital in which the patient had spent the months of November and December, 1927, his temperature chart and clinical record. The temperature chart was striking in that it showed a typical undulant or Pel-Ebstein type of temperature. During the eight weeks he was in that hospital, every alternate week he had a fever to 103-104 degrees, with daily remissions to 100. The weeks between these weeks of pyrexia, he was afebrile. The accompanying temperature charts show the curve at the two periods of his illness. He was discharged, in one of his afebrile weeks, as cured of typhoid fever with four relapses. No Widal test was done and he probably continued to have febrile and afebrile periods after discharge from hospital. The disease was clearly not

typhoid and our Widal test being negative, one was justified in ruling it out as the cause of his illness

The Pel-Ebstein temperature curve could be produced by a granuloma (Hodgkin's disease), *Brucella abortus* infection, or, very improbably, tuberculosis. No evidence of the enlarged glands of Hodgkin's disease was found, and they, therefore, must be abdominal if present. The differential count, with no increase in

endothelial cells, was against Hodgkin's disease. Through the kindness of the Connaught Laboratories, University of Toronto, we were able to have agglutination tests done with *Brucella abortus* and *Brucella melitensis*. Positive agglutination with *abortus* 1200 and with *melitensis* 180 were reported. A positive diagnosis of *Brucella abortus* infection was then made.

The patient's temperature reached normal about June 1st, his appetite improved and he was discharged from hospital. Stereoscopic plates of his chest were taken again, and the minimal tuberculosis was found unchanged as compared with the previous plates. The blood Wassermann test was negative. Blood examination on discharge was similar to that taken at time of admission, except for a slight increase in the anaemia. Blood white blood cells 6,000, red blood cells 3,500,000, haemoglobin 75 per cent (Sahl). Smear polymorphonuclears 48 per cent, lymphocytes 43 per cent, monocytes 9 per cent.

Further agglutination tests done by the Connaught Laboratories gave an agglutination of 1200 with *Br. abortus*. Blood sent to this laboratory for culture showed the presence of *Br. abortus*.

This case is a mild, undulant type of *Brucella abortus* infection in man, proved by positive blood culture and agglutination tests. The patient was at no time very ill, yet he was incapacitated for about ten months. The outstanding clinical points were that the patient looked so well when he had a high fever, the presence of drenching sweats, the Pel-Ebstein temperature curve, the marked remissions in temperature from 104 to 99 degrees in a few minutes, the presence of mild phlebitis and arthritis and the constant leucopenia, with a relative lymphocytosis. One can easily understand why such a case could remain undiagnosed, particularly, if the patient was not observed during the period when his temperature showed

the Pel-Ebstein or undulant type of temperature curve.

The patient, though he came from Italy, had no illness while there, and there was a period of months after he arrived in Canada before this disease began. We, probably, are justified in saying that he became infected in Canada from unpasteurized milk. The actual source of his infection was not traced.

CASE 2

Mrs F, aged 52 years, she came to this country from Italy, sixteen years ago. There was no history of any illnesses in Italy. Her past sicknesses included typhoid fever in 1923, which from details obtained was, probably, correctly diagnosed. No other members of her family were ill.

She was first seen June 1, 1928, complaining of feeling feverish, with headache and profuse perspiration. She had a slight cough with sputum. On questioning her regarding her illness, she was in good health, apparently, until January 1, 1928, when she had a severe chill with fever. She then volunteered the information that since January she had been sick every alternate week with a fever, headache, and general malaise, one week she would be so sick that she would have to stay in bed, the next week she would feel well and be able to do her housework. These alternating periods of ill health with fever and feeling of good health without fever lasted from five to seven days each and had persisted regularly since January. During her five months' illness, January to June, she had had slight, vague aches in her back and legs. No painful or swollen joints, and no phlebitis were noted. She had lost very little weight and did not consider herself very ill, except that she could not understand why she should be sick so regularly, every alternate week.

Physical Examination—The patient did not appear to be ill. The chest examination was negative, except that the heart was enlarged 10 cm to left in the 5th interspace, no murmurs. The blood vessels were slightly sclerosed. Blood pressure, 50/90. In the abdomen nothing was abnormal, the spleen was not palpable, the liver, not enlarged. The joints, peripheral nerves, and glands were apparently normal. Temperature 104°, pulse 90. Blood white blood cells 5,000, red blood cells 4,000,000, haemoglobin 80 per cent. Differential count polymorphonuclears 69 per cent, lymphocytes 23 per cent, monocytes 6 per cent. A catheter specimen of the urine contained a trace of albumen, an occasional pus cell, and granular casts.

A provisional diagnosis of *Brucella abortus* infection was made, and blood was sent to the Ontario Laboratory, Toronto, for agglutination. The blood showed positive agglutination in 1320 with *Br. abortus* and in 1160 with *Br. melitensis*.

Progress—During the time the patient has been under observation, since June 1st, she has had one period of six days with continuous fever, with daily variations from 104 degrees to 100 degrees. This was followed by a week with no fever and no symptoms. The following six days she again ran a daily fever, to 103 degrees with remissions to 100 degrees. Since then, for two weeks, she has remained afebrile and without symptoms. A constant leucopenia was present, but without relative lymphocytosis.

This case has many points of difference from Case 1. The patient was never very ill, and during her afebrile periods she was symptomless. She greatly aided in the diagnosis by remarking

that every second week she was ill with a fever. Unfortunately, temperature charts were not available, as she was not ill enough to have nurses or to go to hospital, but from the history and the occasional temperature records obtained she, undoubtedly, would have shown a typical Pel-Ebstein temperature curve. The mild nature of the infection, probably, accounts for this case going undiagnosed for five months, although on only two or three occasions did she think it necessary to consult a physician. She stated that the only milk she had used for years was pasteurized milk from a local dairy. It was impossible to ascertain the source of her infection.

CONCLUSION

In June, 1925, five cases in human beings of *Brucella abortus* infection, occurring in Canada, were reported as preliminary reports. The cases cited here, the first to be reported in detail, make a total of seven. It is highly probable that many more have gone undiagnosed.

The Board of Health, by making it possible to have agglutination tests for *Brucella abortus*

done on specimens of blood showing a negative Widal, can greatly help in the detection of more human beings suffering from this infection.

The varied symptomatology and the clinical course of the infection in man have undoubtedly, caused many cases to go undiagnosed. It is even possible that the organism in a primary focus may cause secondary lesions in the joints and nerves, without marked evidence of a generalized infection. This is suggested in the finding, by Carpenter, of *Brucella abortus* in seven out of fifty-five pairs of human tonsils, cultured after removal.

AURICULAR FLUTTER RESTORED TO NORMAL RHYTHM BY QUINIDINE*

WITH THE REPORT OF A CASE

By C. R. BOURNE, M.D.

Montreal

THE interest in this report lies in the type of disturbance of cardiac mechanism and the method of its restoration to normal.

CASE REPORT

The patient, aged 38, was a private in the 22nd Regiment during the war. Since demobilization he has worked as a plasterer.

Personal History—No definite history of rheumatism or lues, prior to the present illness he had had repeated attacks of sore throat. About two and a half years ago he had to stop work on account of dyspnoea, oppression in the chest, and cough. After a fortnight's rest, at home, he was able to return to work, but was soon laid up again. Alternate periods of rest and work followed for two years and a half,

until admission to hospital under Drs. C. A. Peters and D. G. Campbell, on December 22, 1927.

Complaints—Breathlessness, precordial pain, cough and oedema of the legs of moderate degree.

Present Condition—He also showed arrhythmia and a soft apical systolic murmur, with a few crepitations at the bases, but no gross heart failure. The Wassermann reaction was negative.

When at rest the ventricular rhythm was either regular, at about 75 per minute, or irregular, between 75 and 110. With exercise or excitement the rhythm became regular, at the rate of 150, but soon became irregular and slowed with rest. As the pulse slowed after this acceleration, the intervals seemed to bear a mathematical relation to one another. They lacked the gross irregularity frequently found in fibrillation of the auricles. A series of rapid

* From the service of Dr. A. H. Gordon, Montreal General Hospital.

regular beats would be followed by others, once and a half or twice as long, and this same phase of irregularity was frequently repeated. When the patient was at rest and the pulse slow, regular undulations could be detected in the jugulars, occurring about four times as fast as the ventricular rate.

The peculiarity of the irregularity, and these cervical undulations, were suggestive of auricular flutter, and an electrocardiogram definitely established the diagnosis.

FIG 1—Electrocardiogram showing flutter of the auricles, on admission, December 22, 1927. Leads II and III show rapid waves marked "P" representing the "circus movement" of the auricle at the rate of 288 per minute. Every second or third "P" wave gives rise to a ventricular deflection (R) as shown by the black lines below. The other "P" waves, marked with dotted lines, are "blocked" and do not reach the ventricle. Note the sequence of intervals 233233, such an arrangement is characteristic of flutter.

TREATMENT

He was kept in bed and tincture of digitalis was given for six weeks after admission, the result was slower and more efficient ventricular action, and a more comfortable patient, though flutter still remained, the auricular rate remaining about 300 per minute. During the latter weeks he was able to be up about the ward for a portion of the day. Four and one-half ounces of the tincture were given, in all.

FIG 2—After five days' rest in bed on tr digitalis on 10, t.i.d. Patient much more comfortable, though the ventricular rate is unchanged. The auricles are beating more rapidly (320 per min.), the vagal being the pre dominant effect of the digitalis. Note the alternation of 2:1 and 4:1, response of ventricle to auricle in the leads I and II. This sequence was heard at the heart

and felt at the radial, and is characteristic of flutter of the auricles. The regular 4:1 response in lead III is frequently seen when a flutter patient is at rest. The absence of "P" waves in lead I, (transverse) is due to the relation of the "circus movement" to this lead and is not uncommon in flutter.

FIG 3—The upper line is taken at rest in bed after six weeks of tr digitalis (4½ ounces). The ventricle is regular and more efficient and slowed to 75 per min. The auricular rate remains at 300 (4:1 response). The second and third lines show the effect of moderate exercise, with the abrupt doubling of the ventricular rate to 150 per min but no change in the auricle (2:1 response). The effect of exercise soon ceases and the fourth line, taken within two minutes, shows the effect of rest, with a slower ventricle, alternating as in Fig 2. Shortly afterward the rhythm returned to that seen in the upper line. This effort response is typical of flutter of the auricles.

Quinidine was started several weeks after entering hospital, a preliminary dose of two grains of the sulphate and then four grains every four hours. Almost immediately the auricular rate was slowed by one-sixth. The drug was well borne. The patient was kept in bed throughout this treatment. The drug was increased to six grains every four hours and when 226 gr had been given the auricular rate was 180, which was probably slower than it had been in more than two and a half years. The ventricle, however, was beating at 90, which was not so slow as under digitalis. The dosage was increased to 8 gr every 4 hours (32 gr a day),

FIG 4—Quinidine sulphate therapy, February 14, 1928. Preliminary dose of 2 gr and then three 4 gr doses at 4 hour intervals. Tracing shows immediate slowing of auricular rate (P) to 252. In the middle line there is a regular 4:1 flutter, with the ventricle beating at 63, but irregularity is more usual with quinidine, as shown in the upper and lower lines.

FIG 5—After 8 days of quinidine, gr vi, q 4 h (Total 225 gr) Flutter 2:1 The auricle is slowed to 180 per min, the slowest of the series, the ventricle is now more rapid (90) than when under digitalis

and this dosage was continued for five days up to a total of 500 gr The patient had only a slight headache with little, if any, nausea, and a slight icteroid tint The toxic effect of the drug became evident in the tracing (see Fig 6) and drugs were stopped for a short period

FIG 6—February 28, 1928 After 500 gr of quinidine, gr 8 q 4 h, latterly Auricular rate 200, ventricular rate 90 Aberrant ventricular beats (x) indicate the toxic effect of the quinidine

Combined digitalis and quinidine therapy in large doses, one dram, and 8 gr, respectively, every 4 hours, was tried, but soon stopped on account of nausea, and smaller doses of 10 minims and 4 gr were borne for two days only, when headache, nausea and anorexia led to stoppage of this regime

After a two-days' rest from all drugs, another course of quinidine was started on March 16th, with 4 gr, q 4 h, for a few doses and then 6 gr, q 4 h Three days after starting this course normal rhythm was restored, with a total dosage of 750 gr of quinidine (500 gr in the first course, 100 gr, combined with digitalis in the second course, and 150 gr in the last and successful course) The patient remained in bed in the ward for five weeks, with gradually decreasing dosage of quinidine, until 4 gr three daily were given, and he is still receiving this amount

Dr A H Gordon made the following note on the patient's condition "On the day following restoration to normal rhythm the external jugulars were much distended and pulsating with a systolic rhythm Each vein was the size of a thumb At the same time pulsation in the liver was demonstrated, but this was regarded

as cardiac systolic ventricular pulsation, communicated A systolic apical and substernal murmur was noted Patient had no distress This jugular pulsation gradually diminished and before discharge was scarcely recognizable "

On discharge the patient stated that he felt more comfortable than for several years X-ray demonstrated cardiac enlargement to the right and left The diagnosis was mitral endocarditis, auricular flutter, cardiac decompensation and tricuspid regurgitation

He was advised to lead a sedentary life in the open air for six months at least, and to continue taking 4 gr of quinidine three times a day during this period Two months later he reported at the cardiac clinic at the Montreal General Hospital There was no distress He had followed the regime advised The pulse was regular and the rate 72, and the tracing was normal

FIG 7—Normal Rhythm, March 19, 1928, after two courses of quinidine, of approximately 500 and 250 gr (total 750 gr) The patient was taking gr 6, q 4 h, when offset from flutter resulted in return to normal mechanism

DISCUSSION

In auricular flutter¹ the normal cardiac mechanism is wholly in abeyance Regular contraction waves travel clockwise, in a ring of auricular muscle around the venæ cavæ The wave completes the same circuit over and over again in this ring, supplying the impulse to the remaining auricular tissue at each of these "circuit movements" The conditions favourable to the establishing of circuit movements are, (a) a large ring of muscle involved, (b) a slow rate of conduction, and (c) a short refractory period

The ventricle beats at a slower rate, usually one-half, though, as a rule, in response to the auricle Acceleration and heart-block are combined, therefore Flutter may occur in short paroxysms but is more frequently persistent, lasting for months or years when untreated It is closely related to fibrillation² of the auricles

and often becomes changed into it. Experimentally, flutter may be produced,³ at times, by repeated stimulation of the auricle by rapid and rhythmic shocks. Clinically, it may be associated with rheumatic heart disease, influenza or other infections, lues and infections of the urinary tract, arteriosclerosis, coronary sclerosis and hyperthyroidism. Though seen for the most part in elderly subjects, it is also met with in quite young children and in adults of all ages.

A regular tachycardia with a fixed rate between 120 and 160 per minute which persists for over a fortnight, is almost certainly flutter. Where flutter is continuous, the symptoms vary according to the ventricular rate and the state of the heart muscle. In many patients there is little disturbance, in these the ventricular action is slow and the muscle relatively strong. In others, when the ventricle is rapid there is dilatation of the heart, cyanosis, venous engorgement, enlargement of the liver and dropsy. The importance of flutter, clinically, lies in the rate engendered in the ventricle.

The influence on life is indefinite, though its persistence for eight years has been recorded, with the ventricle beating continuously at 150. The first case studied by Lewis "fluttered" from 1914 to 1926.⁴ Severe congestive failure was relieved by digitalis in the first month of treatment, but drug treatment was refused after this time, and the patient was able to be about and had no further gross congestive failure. Speaking generally, the most important guide to prognosis before treatment is the degree of tolerance shown to flutter, *i.e.*, whether or not it rapidly induces congestion or heart failure. Response to treatment itself greatly influences prognosis. A useful existence is seldom possible, unless a normal rhythm is restored and maintained. Flutter, persisting in spite of treatment, induces great incapacity and high mortality.

Digitalis alone restores flutter to normal rhythm in one-third of the cases, and in another third it induces fibrillation. Withdrawal of the drug may then give a normal rhythm. Flutter may return and require a further course of digitalis. Digitalis slows and strengthens the ventricle, and may be pushed until the ventricular rate reaches sixty or even fifty.

Quinidine acts by lengthening the refractory period. It also slows conduction. The normal rhythm can be restored in flutter only by closure of the gap between the crest and wake of the oncoming wave. Success probably occurs only when the effect on the refractory period predominates. Quinidine converts established flutter to normal rhythm in 20 per cent of cases. Where digitalis has left the auricles fibrillating, quinidine may convert them to normal. An undesirable rapidity of the ventricular rate is an occasional accompaniment of quinidine therapy. Quinidine is contra-indicated with a history of hæmoptysis, venous engorgement, or with much enlargement of the heart.

It is stated that intramural thrombi may be formed during long paroxysms of flutter, and then expelled on the return to normal auricular activity under quinidine. In our case the period of flutter had exceeded two years and quinidine caused none of these untoward results. It would seem wise, however, to recognize this danger by confining to bed any patient under active "cinchonization."

SUMMARY AND CONCLUSION

1 In a young subject under forty years of age with established flutter and a heart definitely enlarged, but without gross cardiac failure, there was a marked tolerance to quinidine, and massive dosage (750 gr.) restored the normal mechanism of the heart beat.

2 Digitalis improved the ventricular action but apparently deserves little, if any, credit for the offset of flutter.

3 Combined digitalis and quinidine therapy was poorly borne.

4 In a person under forty, with a heart relatively healthy, normal rhythm is so desirable that quinidine should be tried first, but in other cases foxglove should have first choice.

INJECTION OF AIR BY THE LUMBAR ROUTE IN DIAGNOSIS AND TREATMENT*

By J NORMAN PETERSEN, M D ,

Montreal

WE recognize in roentgenology a valuable aid in the diagnosis of certain neurological conditions. By this means we can detect changes in the sella turcica due to intra- or supra-sellar pressure, changes in the suture markings due to increased intracranial tension, and injury or disease of the bones of the skull and vertebral column. Our difficulty has been, however, that the structures within this osseous cavity are of such uniform density or opacity that their various parts cannot be differentiated and lesions cannot be demonstrated. Rarely does a brain tumour become manifest on x-ray examination and, when it does, it is because of calcified areas which it contains, or because of its encroachment upon and involvement of the bony structures, or its obliteration of the air spaces in the nasal accessory sinuses.

Within the past decade attempts have been made to overcome this difficulty by injecting into the spinal fluid circulation, or by substituting for the spinal fluid, substances which will cast a shadow different from that of the intracranial and intra-vertebral contents themselves, and consequently will show distortions or other abnormalities of the spaces normally occupied by spinal fluid. We will dismiss with a word the first of these methods. In 1921 LaFay originated the iodine-containing vegetable compound lipiodol. In the same year Sicard and Forestier, finding that this was opaque to the roentgen rays and non-irritating, injected it into the lumbar sub-arachnoid space and by this means demonstrated a spinal cord compression. Since that time it has been widely used, and cases have been shown here in Montreal, by Russel and others, of cord tumours localized by this means. The lipiodol is injected into the cisterna magna and pictures taken with the patient in the upright position, or into the lumbar space, in which case the patient is turned upside down.

HISTORY

It was Dandy who first tried replacing the spinal fluid, and the medium which he used was air. In studying some cases of hydrocephalus in infants he found that by puncturing the ventricles, withdrawing the spinal fluid, and injecting air, he could get very good and extremely valuable pictures of the ventricular system. Often, by this means, he was able to determine the point of obstruction in patients with obstructive hydrocephalus. Desiring similar outlines of the basilar and pontine cisterns, he next tried injecting the air by the lumbar route. He came to the conclusion that of the two methods the latter was the more dangerous, and so it was given up for several years on this continent. He called the first of these operations "ventriculography" and the second "encephalography." In Europe however the procedure was carried on with greater enthusiasm, notably by Bimgel and Wideroe. Several authors reported upon it and many cases were described without a fatality. In 1922, Schoot and Eitel drew attention to some of the ill effects which might follow encephalography. They noticed nausea and vomiting, pallor, sweating, shock, and sometimes fever, and an intense desire to defæcate. Since then the literature has been accumulating, both in Europe and, more recently, in America.

While encephalography was for some time in dispute in the new world, ventriculography at once took its place in the diagnostic methods of the neurological surgeon. Grant, in an excellent critical review in 1925, discussed the two methods and analyzed the results in 392 collected cases of ventriculography. He concluded that the condition in which an injection is most desired is brain tumour, especially if localization is difficult by other means. But it is just in these cases, cases with increased intracranial pressure, that encephalography is dangerous and contra-indicated. He admits the

* Presented to the Neuro Psychiatric Society of Montreal, April 4, 1928

possibility of getting good photographic results in other conditions, but these are not amenable to treatment. His analysis yielded interesting data in regard to ventriculography. In his series positive information as to the position of the tumour was obtained in roughly 80 per cent of the cases. In 30 per cent of these all other evidence as to the location of the neoplasm was lacking. Of the 93 cases thus localized by ventriculography, in the absence of neurological evidence, 44, or nearly 50 per cent, of the growths could be removed by surgery. Less than 1 per cent of the operations were performed uselessly owing to misinterpretations of the air shadows. The mortality rate is high, more than 8 per cent, but less of course than that of unextirpated brain tumours.

In the last few years greater enthusiasm has been exhibited in encephalography on this continent. Martin and Uhler reported a series of 14 cases without a fatality. Carpenter has published a report of 40 cases. Waggoner presented a series of 10 before the Philadelphia Neurological Society, and Friedman and Kasanin reported 45 cases at the 1927 annual meeting of the American Neurological Society. Their series included a child of six months. At this meeting comment was in favour of the procedure. All are agreed that, when properly carried out on selected cases, it is practically devoid of serious results.

TECHNIQUE

Several methods of removing the spinal fluid and injecting air have been described. I have used that outlined by Waggoner. Carpenter advises that the interchange be carried out with the patient under ether-anæsthesia, but most workers use nothing apart from the local anæsthetic injected before the lumbar puncture needle is inserted. Before leaving the ward for the x-ray room the patient is given morphine gr 1/4 and atropine gr 1/150 or less, according to age and weight. When he reaches the x-ray room he is prepared, and an ordinary lumbar puncture is done, in the sitting position. The needle is inserted in the third lumbar interspace. The head of the patient should not be flexed too much, as this prevents the proper diffusion of the air. It is well to have the nurse stand in front of and close to the patient in case he needs support, perhaps

for mutual support, for although I have seen the nurse faint dead away I have never known a like fate to overtake the patient.

When the meninges have been penetrated, the spinal fluid pressure is taken and then the interchange begins. To the shoulder of the lumbar puncture needle a three-way stop-cock is fixed the side outlet of which leads to a closed glass cylinder of about 200 c c or more capacity. To the horizontal outlet an ordinary Luer syringe is attached. Into the syringe are slowly drawn 5-10 c c of spinal fluid, the stop-cock is turned and the fluid is discharged into the cylinder. Immediately 5-10 c c of air are drawn into the syringe from the cylinder, the stop-cock is again turned and the air injected into the sub-arachnoid space. The remainder of the procedure is just a repetition of these acts. It is important to take the pressure of the spinal fluid frequently, at least after the withdrawal of every 25 c c and, as one approaches the end, more often. Opinion varies as to the relative amounts of fluid to be withdrawn and air injected, but is unanimous that the pressure should be the criterion. If possible, this should be kept constant. I have found that it tends to fall, and that one invariably ends up with a pressure considerably less than the original. For this reason I agree with Carpenter that about 10 per cent more air can be injected than fluid withdrawn, though most writers feel that the ratio should be reversed. In this regard it has been pointed out that the air is taken at room temperature and injected into surroundings of body temperature with a consequent expansion. In the ordinary adult about 100 c c or 120 c c are introduced.

The procedure is tedious, alike to patient and physician, and usually takes about forty-five minutes to complete. In the case in which I encountered least difficulty the entire process lasted about twenty minutes. I have found that the fluid is usually difficult to get after 40 c c or so have been withdrawn, and then must be taken off in small quantities at a time. During the operation the patient almost invariably complains of headache at the base of the occiput, and this may become severe. In addition, the reactions which Schoot and Eitel described may be encountered, though I have seen only pallor, headache, sweating and

nausea It may be necessary during the interchange to give the patient whiskey or aromatic spirits of ammonia to overcome his sense of insecurity

It is well to have the subject, during all of this, seated on a stretcher with wheels, so that he may be immediately brought to the x-ray machine with a minimum of disturbance and movement It is important that, while the pictures are being taken, the patient's head should be kept absolutely in a perpendicular plane, otherwise unequal diffusion of the air will take place and distortion of the ventricular shadows result Lateral views are taken from each side, and an antero-posterior exposure with the film at the occiput, the head very slightly flexed, and the tube directed about the hair line, so as to avoid superimposing the shadow of the frontal sinuses on that of the ventricles The patient is then returned to the ward, made to lie flat in a bed, the foot of which is raised, and given another hypodermic injection of morphine, if this is necessary Weigeldt has stated that in cases without obstruction to the aqueduct of Sylvius or the foramina of Luschka and Magendie air in the ventricles is absorbed in eight to ten hours and, following encephalography, unpleasant sequelæ rarely last longer than that

INDICATIONS

There are two contra-indications to this method of air injection, (1) increased intracranial pressure, and (2), posterior fossa tumours In these cases, however, some surgeons perform a combined puncture The ventricle is tapped, fluid is released to overcome the increase in tension, and air is injected into the subarachnoid space in the lumbar region The only encephalography to end in death which I have seen was such a combined puncture, done on a patient with no clinical evidence of increased intracranial pressure, but with a massive infiltrating tumour of the right parietal lobe A lumbar puncture was done about five hours after the combined puncture and an injection At this time spinal fluid gushed out, only a little was removed but apparently the medulla and cerebellum acted as a sufficiently tight plug to prevent fluid escaping from above, and, when the man died about ten hours later, a hernia through the

foramen magnum was found Such a case would have offered a bad prognosis even for ventriculography alone, and still worse, of course if no intervention had been attempted

This procedure has been followed and recommended in many conditions Carpenter writes of its use in cases where diagnosis is otherwise doubtful, in petit mal, convulsions, chronic headache, occasional cases of mental impairment, certain head injuries, etc In 40 cases in which he did encephalography, 19 presented normal findings, 21 abnormal pictures, and 1 died In 23 trephine cases he had 4 normal, 19 abnormal and 3 died Focister, in addition, has applied lumbar air injection, suboccipital puncture, or ventriculography, in such conditions as hydrocephalus, infantile palsy, tumour, pseudo-tumour, encephalitis, etc Wartenburg adds post-traumatic neurological and psychiatric disorders, dementia paralytica, and suggests its use in differentiating organic from functional hemiplegia As you can readily appreciate the procedure has been employed in practically all available neurological conditions Let us turn now to the results obtained

INTERPRETATION

The interpretation of the results obtained by encephalography demand the attention of an expert radiologist used to this kind of work One looks for variations in the size, shape and position of the ventricles, and for abnormal collections of air, either too little or too much, in the cisterns and in the subarachnoid space surrounding the cortex Numerous reports have been made of the shadows encountered Elsberg and Silbert, after having made casts of the ventricles in cases of brain tumour, and having compared them with the ventricular shadows obtained beforehand, drew the following conclusions In posterior fossa lesions the ventricle contralateral to the growth is regularly more dilated than that of the same side On the side of the tumour the posterior horn is consistently shorter, and is displaced forward and outward as compared with the other This displacement of the homolateral posterior horn may account for the unilateral papilloedema in some cases of tumour In infiltrating tumours of the cerebral hemispheres the lobe in which the growth is located is often larger than the other The vertical planes of the anterior

and inferior horns, in cases with hyperplasia of the hemisphere, are either collapsed or separated more than normal on the side of the tumour, while on the opposite side they are more closely approximated to each other. When there is no hyperplasia the relation of the horns to one another remains unaltered.

Hyperplasia is rarely present in dural tumours and rarely absent in infiltrating growths, therefore, separation of the vertical planes may be of diagnostic value. In comparing supra-tentorial and infra-tentorial lesions the authors found that hydrocephalus occurring with the latter caused relatively little dilatation of the temporal horns, as compared with the anterior horns and bodies of the ventricles. In supra-tentorial lesions dilatation of the inferior horns was as great or greater than that of the others. They were not prepared to say how universal is this finding.

Turning to conditions other than neoplastic, we find Foerster describing dilatation of the ventricle on the side of vascular lesions, dilatation of the ventricle on the side of focal lesions in epilepsy with convulsions beginning in a particular part, and widening of the subarachnoid spaces with dilatation of the ventricles in pseudo-tumour, often owing to infectious or traumatic meningitis. In epidemic encephalitis he also found dilatation of the ventricles. He points out the value of encephalography in differentiating obstructive and communicating types of hydrocephalus, as in the former little or no air will get into the ventricles, and the point of obstruction may be seen. Wartenburg found that following trauma to the skull, even without fracture, there is often widening of the ventricle on the side of the lesion with a rounding off of the upper angle of the "butterfly figure" which is normally assumed by the shadow of the bodies and anterior horns of the lateral ventricles. This angle shows a tendency to wander towards the site of the lesion, when the projection of the angle is towards the superior portion of the brain the signs point more to involvement of that part, when it bends on itself and extends towards the ear the signs point to an involvement of an inferior level of the cortex. In cerebral infantile palsy he states that there is constant widening of the ventricle on the affected side together with large sub-

arachnoid spaces. Encephalography may be used also in attempts to localize tumours causing pressure on the spinal cord, in some of which cases the arrest of air within the intravertebral canal will indicate the point of compression.

It is important to bear in mind that in some of these conditions such marked and definite post-mortem changes are not found, and it would be unwise to lay too great stress on the nature of the changes observed after air injections, until the variations that may occur in the normal are known. It is true that different conditions prevail at these different times, and that encephalography allows a study of what Foerster describes as the "anatomy in vivo." Monrad Krohn, whom I quote from memory, in discussing the paper of Friedman and Kasanin, said that after having carried out this procedure he had come to the conclusion that one could not depend on an equal and uniform diffusion of the air throughout the ventricular and subarachnoid systems, but that after hearing the paper and the discussion it provoked he was inclined to try encephalography again.

TREATMENT

The use of lumbar air injection in treatment is more recent than that in diagnosis, to which the foregoing discussion has been confined, and I have had no personal experience with it. As a result, it will be referred to only briefly. The condition in which it has been used most, and for which best results have been claimed, is post-traumatic headache. It has also been employed in epilepsy, the sequelæ of encephalitis, and other post-traumatic conditions. The technique is the same as that here described, and a similar amount of air is injected. Wartenburg reports subjective improvement in a surprising number of cases, and Carpenter reports three cases of severe chronic headache cured by this means. He says that several other disturbances improved after encephalography without other treatment, and offers as explanation either distension of the membranes or reaction from the presence of the air. Penfield has treated seven cases of post-traumatic headache by means of lumbar air injection. At a recent meeting of the Montreal Medico-Chirurgical Society Malcolm showed two cases

in which he had obtained gratifying results

I wish to present briefly three cases in which encephalography has been employed as a diagnostic measure

CASE 1

The patient a man of 56 years had in January 1925, a febrile illness in which he shook or shivered all over. The left arm and leg shook more than the right. For two weeks after the onset he had weakness of the left side of his body and did not have sufficient strength to hold things in his hand. He had frontal headache at times. In April 1925, he developed a cramped, painful feeling in the left arm, left leg and left side of the face, which was followed immediately by unconsciousness lasting fifteen minutes. During the attack both arms and both legs underwent jerking movements. He had eight such attacks from April 1925, to May 1926, and fewer since. He was admitted to hospital on December 12 1927. The history in this case was very indefinite, the real duration of the attacks could not be accurately determined and the nature of the initial febrile illness was obscure.

Examination showed a tendency for the tongue to protrude slightly to the right, a weakness (?) of the left side of the soft palate, and weakness of the left arm and leg. The tendon jerks were increased on the left as compared with the right. Memory was impaired so much so that he could not tell whether his illness had begun in 1925 or 1926. X-ray of the skull, examination of the fundi and spinal fluid Wassermann were all negative. The cerebrospinal fluid gave a one plus Pandy reaction, and reduced colloidal gold (123200234). Dr Bromer's report of the encephalogram is as follows: "Examination by encephalogram shows a complete lack of sub-arachnoid air in the right half of the skull. The left shows a normal amount of sub-arachnoid air. The right ventricle has an obviously deformed outline, somewhat flattened and thinned. The left is distorted and widened. I think that this is strong evidence of neoplasm, probably glioma on the right side." The patient is still under observation in the outpatient clinic.

CASE 2

The patient, aged 31 years, was admitted to hospital on October 22 1926, with the following history. In 1918 while bumping a football with his head, he suffered a fracture of the skull. For three months after this he had total paralysis of the left side, and for six months numbness on this side. He improved and returned to work. In May 1926 he lost control of his left arm while working at his dining. The weakness in this member grew progressively worse. On extension of his arms, he showed a coarse, wavelike movement of the entire left arm. The left side was weaker than the right, and this was most marked in the leg. The tendon jerks on the left were increased as compared with the right. Examination of the eyes showed nystagmus, but nothing else abnormal. Lumbar puncture, shortly after admission yielded a spinal fluid with 11 cells per cmm, a two plus Pandy reaction, a negative Wassermann and a reduction of colloidal gold in the paretic zone (5555533000). It was thought at first that he had a cyst resulting from his old accident.

The report of an X-ray of the skull taken on October 22, 1926, is as follows: "Sella measures 4 mm by 8 mm in depth and is normal, convolution markings are normal no other abnormalities can be seen." An encephalogram was done and it was at first believed to present evidence of a fronto-parietal tumour. Re-examination however dispelled this belief, and attributed the previous findings to the fact that the patient's head had been tilted. On November 16 1926 Dr Bromer made his final report which follows: "On final examina-

tion, the lateral ventricles on each side are more nearly of the same size and shape. The head was tilted downwards on the left side and in consequence on the films the antero-posterior view shows the left ventricle only slightly wider than the right and with slightly more blunted horns. (See Fig 1) The stereoscopic lateral

FIG 1—Case 2—Encephalogram antero-posterior view

views show no great difference apparently in the ventricles. I think this second examination practically rules out the possibility of a tumour in the fronto-parietal region as was suggested by the previous films. The sub-arachnoid spaces on the left are also more completely filled with air than on the right. The occipital area in the lateral view has also a little more air as compared with the frontal and parietal areas. I doubt however that this means brain atrophy." (See Fig 2)

FIG 2.—Case 2—Encephalogram, lateral view

During his stay in hospital the patient gradually developed into a most marked and typical case of multiple sclerosis, presenting numerous signs including Charcot's triad of symptoms.

CASE 3

This patient a seven-year-old Italian girl, was admitted on September 21 1926, with a diagnosis of epilepsy. Her development was normal until 1920 when she had a generalized convulsion followed by weakness of the left arm and leg lasting a day or two. Since then she had had several attacks a year. On examination, the right pupil was larger than the left and both

were very irregular. There was a droop to the left side of the mouth, and the left side of the soft palate moved less than the right. A coarse, rapid, lateral nystagmus was present when the eyes were turned to either outer canthus, more marked when turned to the left. The fundi were negative.

Encephalography was done on October 27, 1926, with the following results: "The anterior horn of the right lateral ventricle is wider than normal, more distended than the left. The posterior portion of the right is much enlarged, and is circular in shape extending upwards and backwards. The left ventricle is

narrowed and distorted also in shape, resembling a compression distortion. The midline septum is not bulging or distorted, however. Very little subarachnoid air (see Fig 3) can be seen on either side. These changes could be due to an internal hydrocephalus involving the right ventricle or to a porencephalon cyst. There is no apparent brain atrophy. The third ventricle is obliterated but the fourth can be seen, however." (See Fig 4)

CONCLUSION

In encephalography we have a useful method of examination and of treatment, the full value of which is not yet demonstrated, but I cannot brush aside the criticisms of Grant with which, in large measure, I agree.

I desire to thank the Philadelphia Orthopaedic Hospital and Infirmary for Nervous Diseases for permission to present this clinical material, Drs Burr, Sinkler and Weisenburg, from whose services the cases were taken, Dr Ralph S. Bromer, the radiologist there, and especially Dr Joseph Michaels, resident neurologist, who kindly collected the plates, abstracted the records, and forwarded all to me.

Plato in his "Republic," Book III, turns prophet, and draws a splendid picture of the day "when our youth will dwell in a land of health, amid fair sights and sounds, and receive the good in everything, and beauty, the effluence of fair works, shall flow into the eye and

ear like a health giving breeze from a purer region, and insensibly draw the soul from the earliest years into likeness and sympathy with the beauty of reason." With all our boasted advance in science and civilization how far short of this ideal do we come to day?

CARCINOMA IN A BLUE DOMED CYST OF THE BREAST*

By L. J. ADAMS, M.D., C.M.,

Montreal

THE patient, a woman of 43, was admitted to the Montreal General Hospital on January 9, 1928

She gave a history of acute inflammation of the right breast while nursing her first child one year previously, and of two blows to this breast at the ages of twenty-one and forty-one years respectively

In November, 1926, she first noticed a small lump in the upper outer quadrant of the right breast. It was then about the size of a pea. There was no apparent change in size until March, 1927, when it began to grow gradually. In July, the surface became reddened, and subsequently the increase in size was more rapid. Early in December there was a fairly large amount of grayish discharge from the nipple with diminution in the size of the tumour. There was no discharge of blood from the nipple at any time, and no loss of weight. Since July, 1927, there had been intermittent pain in the breast, radiating down the arm, but never very severe.

On admission, there was found in the upper outer part of the right breast, a large firm mass measuring $12 \times 12 \times 6$ cm. The tumour was not tender and was freely moveable in the breast tissue. A superficial cyst, dark blue in colour, and about the size of a small egg protruded from the upper part of the mass. There was no deformity of the nipple. There were no palpable glands in the axilla.

A diagnosis of cystic mastitis, with possible malignancy, was made.

Simple amputation of the breast was performed on January 11, 1928. When the tumour was incised, a large quantity of clear light brownish fluid escaped, exposing a multilocular cyst with areas of induration in the wall and slightly papillomatous ingrowths.

The microscopical examination of sections of

fixed tissue confirmed the diagnosis of carcinoma made at the time of operation by means of frozen sections.

The patient was readmitted on February 9, 1928, when a radical operation was carried out. No enlarged axillary lymph-nodes were encountered. Her recovery was uneventful.

SUMMARY OF PATHOLOGICAL REPORT

The specimen consists of a female breast, covered by an oval piece of skin, 22×18 cm in size, with the subcutaneous tissue attached. The external surface is as already described (Fig 1).

FIG 1—Photograph of a wax mouldage of the external surface of the breast. Note the large cyst at superior margin.

The cut section (Fig 2) shows a large cyst measuring 9×6 cm by approximately 2 cm. in depth. It is sharply outlined and well demarcated from the surrounding breast tissue. The large cyst can be seen to communicate directly with the superficial one which is covered by skin only. The wall is very irregular, with an attempt to form smaller cysts. The lining surface is smooth, except for

* From the Department of Pathology, Montreal General Hospital. Read before the staff clinico-pathological conference, March 8th, 1928.

FIG 2—Drawing of the internal surface of the cyst

several hard yellowish gray nodular masses which project into the cavity

Microscopical sections were taken from the breast tissue outside the cyst, and from the smooth and puckered areas in the wall, to determine whether the condition was a large simple cyst with simple papillomatous growths in the wall or one with malignancy

Those from outside the cyst show fairly normal breast tissue for the age period, those from the smooth areas show a thin fibrous wall

FIG 3—Microphotograph showing carcinoma. The section is taken from one of the hard papillomatous areas

Those from the papillomatous areas (Fig 3) show a fibrous connective-tissue stroma, with a

round-celled infiltration and atypical epithelial cells with hyperchromatic nuclei, growing in irregular groups or strands without any definite structural arrangement. There is a great increase of fibrous tissue, as well as large degenerated tumour areas

The second specimen, consisting of a portion of the skin of the breast, 28 cm long, with the underlying pectoralis muscles and the soft tissues from the right axilla, was received on February 8th, at the time of the second operation. Serial transverse sections were made. After diligent search, microscopical examination failed to reveal any carcinomatous involvement of the glands or deeper structures

DISCUSSION

This case was regarded as a large single cyst of the breast of the so-called "blue-domed" type. Grossly, it appeared as a typical benign cyst, but since malignancy has been demonstrated there are several interesting features to note

There is a great variety of classifications of cysts of the breast. In general, it may be said that they vary greatly in size and number. The blue-domed cysts are usually of the large single variety, but they may be multiple. In Bloodgood's series of 350 cases of cystic diseases of the breast, 174 were large single, 28 were large multiple cysts. The blue dome may not be seen until the subcutaneous tissue is cut, the colour being due to the transmitted light from the contents. The wall is smooth and there are, as a rule, no papillomata. Haemorrhage into the cyst suggests malignancy. As to the occurrence of carcinoma, the condition, especially in the large single cysts, is regarded as comparatively rare, about 2 per cent

The etiology of carcinoma in our case, as elsewhere, is not definitely known, but it is interesting that two frequently mentioned factors, namely trauma and infection, were both present. Again, here is a case of cystic disease of the breast with malignancy, in which the nipple was neither scarred nor retracted, but retained a perfectly normal appearance, even though a discharge had taken place from it

The case is unique in that the blue dome could be seen very readily, and was on the external surface by a thin lamina

only Another feature is that, with carcinoma present no blood could be detected in the cyst-contents

Finally, this case emphasizes once more the importance of careful attention to the history of a lump in the breast It also illustrates that

in a large cyst although situated some distance away from the nipple malignancy does occur

PATHS FROM THE PERIPHERY*

By W D M LLOYD, MSc MD, LMCC,

Department of Anatomy, University of Western Ontario Medical School

London, Ont

"The world that I regard is my self, it is the microcosm of my own frame that I cast mine eye on, for the other, I use it but like my Globe, and turn it round sometimes for my recreation whilst I study to find how I am a microcosm, or little World, I find myself something more than the great"—SIR THOMAS BROWNE, *Religio Medici*

THERE are many paths by which the fleeting impulse from the world outside reaches that connoisseur of impulses, the central nervous system These are of the utmost importance, for, as HENRIK¹ has so aptly recapitulated, "The living body is a little world set in the midst of a larger world It leads in no sense an independent life, but its continued welfare is conditioned upon a nicely balanced adjustment between its own inner activities and those of surrounding nature, some of which are beneficial and some harmful" As lowly vertebrates we paid a good deal of attention to these stimuli from the ectoderm They governed our very life, our habits, were instinctive, stereotyped To the dignified mammal of the modern era they are of no less importance The pre-eminence of man is directly due to his ability to cope most successfully with his environment

When we think of the innervation of the comparatively vast skin surface of the human body there are two questions which should present themselves to our minds In the first instance, what nerve supplies each area of skin and, in the second, from what segments of the cerebro-spinal axis do the nerve-fibres supplying this cutaneous area arise? These questions have found their answers in the construction of two diagrams to show the innervation respectively, of the anterior

(Fig 1) and posterior (Fig 2) surfaces of the human body By correlating the work of Henry Head² and Purves Stewart,³ it has been possible to illustrate by diagram upon the same figure the respective nerve and segmental innervation of any part, in a fairly accurate, but, for purposes of simplicity, a very diagrammatic fashion As the essential importance of this knowledge makes its retention by the physician desirable we have sought a simple method for remembering its detail A plan, originally suggested by Purves Stewart, in the main, has been adopted The cutaneous nerve-supply is familiar to most of us because of our visual memory of these fibres during dissection of the body Hence apart from the confusion of old terminology with B N A nomenclature, they may be simply recalled The arrangement of the cutaneous root areas is considerably simplified if we consider the conception that in the trunk they exist mainly in a horizontal series, whereas in the upper limbs they are represented in longitudinal series, parallel to the long axis of the limb, and in the lower limbs anteriorly they exist serially from above downwards and posteriorly from below upwards Finally, the genital organs receive their innervation, as might be expected, from segments caudal to the segments supplying the posterior surface of the lower limb buds, that is from the third and fourth sacral segments If we consider the body as a long cylinder, beginning above at the head (innervated by the trigeminal nerve) and ending below at the coccyx, then the various root-areas may be represented as a series of horizontal dermatomes running from above downwards, with the nose and mouth in the trigeminal area, the nipples

* A lecture delivered to medical students at the University of Western Ontario

at the level of the junction between the fourth and fifth thoracic segments, the umbilicus at the junction of the ninth and tenth thoracic, the last thoracic encircling the area just above the pubes, and the anus within the fourth sacral area. Such a plan of the cutaneous innervation

branches of the ophthalmic division of the fifth cranial nerve, while the integument over the forehead, the superior maxillary and infra-orbital, and inferior maxillary regions of the face, are innervated by the ophthalmic nerve, the maxillary nerve and the mandibular nerve

FIG 1

of the trunk, as simple as that of the round worms, requires modification in only two particulars. In the first instance, it is necessary for us to remember that there is a gap in this segmental innervation between the clavicular region, innervated by the fourth cervical, and the upper pectoral region, supplied by third thoracic segments, where the fibres from the anterior rami of the fifth, sixth, seventh, eighth cervical and first two thoracic segments pass distally to supply the fore-limb bud. Secondly, it is necessary to recall that a similar gap occurs in the lumbo-sacral region between the twelfth thoracic segment, just above the pubes and the third and fourth sacral segments in the ano-coccygeal region, where the anterior rami of all the lumbar and the first two sacral segments pass distally through the lumbo-sacral plexus to supply the lower limb buds.

With this conception of the segmental innervation of the trunk in mind, we find the forepart of the scalp, from a point opposite the external auditory meatus forwards, innervated by

respectively. The back of the scalp behind the level of the external auditory meatus is supplied by the greater occipital from the posterior ramus of the second cervical root, towards the midline, while more laterally it receives its innervation from the lesser occipital from the second cervical segment. The auricular region is supplied by the greater auricular from the second and third cervical segments, its posterior portion also receiving some fibres from the lesser occipital nerve. The medial portion of the back of the neck is supplied by the medial divisions of the posterior rami of the cervical nerves, while the sides and front of the neck are supplied by the cutaneous colli nerve from the second and third cervical segments. The supraclavicular, infraclavicular, acromial, upper pectoral regions, and the skin over the suprascapular fossa of the scapula are supplied by the supraclavicular nerves from the anterior rami of the third and fourth segments of the cervical cord. The skin surface between the upper pectoral region and the level of the nipple is supplied on its anterior

and lateral aspects by the anterior and lateral branches of the third and fourth intercostal nerves, from the third and fourth thoracic segments. The posterior portion of the corresponding area receives its innervation chiefly from the same segments through the posterior rami of the third and fourth thoracic nerves, but in addition receives a few fibres from the muscular branches of the medial divisions of the posterior rami of the fifth and sixth cervical and the first and second thoracic segments (not shown in the diagram). There occurs an oddity of the innervation of the skin surface of the posterior aspect of the trunk, which at this point is well worth noting, in the fact that while the upper part of the posterior aspect of the trunk is supplied by the medial branches of the posterior rami of the spinal nerves, the lower part of the corresponding area below the level of the sixth thoracic segment is supplied by the lateral branches of the posterior rami of these nerves. The skin surface of the body wall between the level of the nipple and that of the umbilicus is about equally divided in its segmental supply between the fifth, sixth, seventh, eighth and ninth thoracic segments, which send their fibres to the back from the posterior divisions of the spinal nerves and to the sides and front through the anterior divisions (intercostal nerves). Between the level of the umbilicus and the

symphysis pubis the abdominal wall is supplied on its anterior and lateral aspects by the anterior and lateral branches of the tenth, eleventh and twelfth thoracic nerves, from the corresponding segments of the thoracic cord. The lumbar region receives a corresponding innervation from the same segments through the lateral branches of the posterior rami of the lower thoracic nerves. Below this level, posteriorly, the skin over the medial gluteal and sacral regions receives its nerve supply through the lateral branches of the posterior rami of the lumbar and sacral nerves, the perineal regions being supplied by the third and fourth sacral nerves, the sacral region by the fifth sacral and coccygeal nerve. Anteriorly, the genitals receive a corresponding nerve supply from the third and fourth sacral segments through the anterior rami of the sacral nerves where fibres at this level arising from the second, third and fourth segments enter into the formation of the pudendal nerve.

If we remember that the upper extremities have grown horizontally outwards from the trunk in the cervico-thoracic region, then it is only reasonable that they should be innervated by segments the fibres of which follow the long axis of the arms, running parallel with those which above and below course band-like about the trunk. Thus, when the arms are held out-

Nervous & Segmental Innervation of the Skin Anterior aspect
— adapted from Wood & Parson's Textbook

stretched at right angles to the long axis of the body, with the thumbs uppermost, the segmental areas are approximately from above downwards C5, C6, C7, C8, T1, and this is true of both the anterior and posterior surfaces of the arm. Since there is so much overlapping in these areas of innervation, we should not be seriously wrong if we divided the arm held horizontally from above downwards, that is from its radial to its ulnar side, into almost equal portions for each of the roots of the brachial plexus of nerves. To this working rule for the segmental sensory innervation of the upper extremity there are two important exceptions. In the first place all the segments sending fibres to the brachial plexus are not represented in the hand, which is divided about equally between the seventh and eighth cervical and first thoracic segments. The seventh cervical segment supplies the thumb and index fingers, front and back, the eighth, the middle, ring, and the contiguous half of the little finger on the front, and only the middle and ring fingers on the back of the hand, while the ulnar side of the little finger on the front and the entire little finger on the back of the hand are supplied by the first thoracic segment. Secondly, it should be pointed out that the inner side of the superior half of the upper arm is supplied by the second thoracic segment through the intercosto-brachial nerve. With these points in mind we are now in a position to consider the sensory nerve supply of the skin of the upper extremity more accurately.

The upper portion of the shoulder cap is supplied by the fourth cervical segment, through the supra-acromial branches of the supra-clavicular nerves. The third cervical segment ordinarily contributing to this nerve is not represented thus far distally. Just distal to this area the remaining portion of the deltoid region is supplied by the fifth and sixth cervical segments through the axillary nerve. The inner side of the upper arm, front and back, from the floor of the axilla to about two inches above the elbow is supplied by the intercosto-brachial nerve from the second thoracic segment. A small area on the inner side of the arm just below the latter, and extending as far as the elbow, is supplied by the medial brachial cutaneous nerve which although it arises from the medial cord of the brachial plexus receives all of its fibres from the second thoracic segment. A large area reaching from the elbow to the

wrist on the ulnar side of the arm, extending over half way across its anterior or volar surface, and about one third of the distance across its posterior or dorsal surface, is supplied by the medial antibrachial cutaneous nerve from the eighth cervical and first thoracic roots. The skin surface of the lateral or radial aspect of the volar surface of the forearm from about an inch below the head of the radius to the base of the thumb, in addition to a small area on the dorsal surface over the lower end of the radius, is supplied by the musculo-cutaneous nerve, the cutaneous fibres of which arise in the sixth cervical segment. The remaining surface on the back of the arm, that is a small area in the mid-line above the elbow, the lateral two-thirds of the dorsal surface of the forearm, together with a small area over the muscular portion of the brachio-radialis at the front of the elbow, is supplied by the radial nerve from the fifth, sixth, seventh and eighth cervical segments. The first thoracic segment usually sends no fibres to the radial nerve. On the front of the hand the little and half of the ring fingers, with their corresponding palmar surfaces, are supplied by the ulnar nerve from the eighth cervical and first thoracic segments, while the ulnar side of the thumb, index, middle and half of the ring fingers, together with the radial side of the palm, are supplied by the median nerve from the seventh and eighth thoracic segments. The fibres from the fifth and sixth cervical and first thoracic roots are not represented in the cutaneous distribution of this nerve. A small area at the base of the thumb, innervated by the musculo-cutaneous nerve, should be included in the sensory innervation of the skin of the hand. On the dorsum of the hand, as on the palmar surface, the little and half of the ring fingers are supplied by the ulnar nerve from the eighth cervical and first thoracic roots. The dorsal surfaces of the distal two phalanges of the thumb, index, middle, and contiguous half of the ring finger are supplied by the median nerve from the seventh and eighth cervical segments, while the rest of the dorsum of the hand, thumb, index, middle and radial half of the ring fingers as far as the proximal interphalangeal joints are supplied by the radial nerve from the seventh and eighth cervical roots. Fibres from the fifth and sixth cervical segments are not carried in this nerve as far as the hand.

In considering the lower extremity we must

think of a quite different plan of innervation from that which obtains in the upper one. If we regard the legs as horizontal outgrowths from the lumbo-sacral region, and visualize them for the moment as strongly rotated from within outwards so that the great toes are uppermost, then the cutaneous root areas are seen to take on a rather segmental arrangement, but in this region, in contrast to the upper limb, the segmentation is in a vertical rather than a horizontal axis, the root areas running from above downwards on the anterior surfaces, and from below upwards on the posterior surfaces of the legs in this position. Thus the various components of the lumbo-sacral plexus are distributed in a very reasonable fashion, in proper sequence from thigh to knee, to leg, to dorsum of foot, to sole of foot, to back of lower leg, to back of thigh. There is but one exception to this plan, which will be pointed out later. The first band-like area, somewhat variable, but measuring a depth of approximately two inches of the skin surface of the thigh, front and back, is supplied by the first lumbar segment. A wide area below this region, extending about half-way down the anterior, medial and lateral aspects of the thigh, is supplied by the second lumbar segment. The rest of the skin surface on the front and sides of the upper leg, as far distally as the level of the upper border of the supra-patellar bursa, is supplied by the third lumbar root. The fourth lumbar segment sends its fibres to the front and inner side of the leg from the suprapatellar region to the ankle, the fifth segment supplying the corresponding area on the outer side and front of the leg from the level of the head of the fibula to the dorsum of the foot. Thus, the area supplied by the fifth lumbar root is lateral to but on a somewhat lower level than the region supplied by the fourth lumbar segment, so that the apparent interruption of the segmental plan, which was referred to above as constituting the only exception, is more apparent than real. The skin over the dorsum of the toes, the sole of the foot, and the back of the lower leg in its lower two-thirds is supplied by the first sacral segment, while the second sacral root supplies the remaining portion of the back of the leg left bare by the lumbar segments, excepting a small area in association with the buttock supplied by the third sacral segment.

Now, keeping this plan of the segmental in-

nervation of the skin surfaces of the lower extremity in mind, we are in a position to consider its more exact nerve supply. A small area of skin on the outside of the thigh, just below the iliac crest and merging on the anterior and posterior surfaces, is supplied by the ilio-hypogastric nerve from the first lumbar segment. The outer and postero-lateral surfaces of the thigh in about its middle third receive their cutaneous nerve supply from the lateral femoral nerve, from the second and third lumbar segments. The upper third of the intermediate zone on the front of the thigh is supplied by the lumbo-inguinal branch of the genito-femoral nerve, from the first and second lumbar roots. A small area of skin on either side over the body and ascending ramus of the pubes is innervated by the ilio-inguinal nerve from the first lumbar segment. The lower two-thirds of the intermediate and the lower third of the lateral zone on the front of the thigh, together with the lower third of the outer surface of the back of the thigh, receive their nerve supply from the intermediate cutaneous branch of the femoral nerve from the second, third and fourth lumbar segments. The medial third of the front of the thigh, from the ilio-inguinal area above to the knee below, is supplied by the medial cutaneous branch of the femoral, from the second, third, and fourth lumbar roots. Two small areas of skin on the inner side of the thigh, an upper one over the origin of the adductor longus, and a lower one at the medial side of the knee, are supplied by the obturator nerve from the second, third and fourth lumbar segments. The inner aspect and inner half of the front of the leg below the knee as far as the lower border of the medial malleolus are supplied by the saphenous branch of the femoral nerve, carrying nerve-fibres only, from the fourth lumbar segment. The anterior and lateral aspects of the outer half of the leg from below the knee to the level of the external malleolus, together with the skin surface over the posterior aspect of the inferior half of the lower leg, receive their innervation from the lateral sural cutaneous branch of the common peroneal from the fourth and fifth lumbar and first sacral segments. Fibres from the second sacral nerve, carried in the common peroneal trunk, are not represented in this nerve. The skin surface over the dorsum of the foot, except the integument

over the little toe, the tips of all the other toes, the adjacent halves of the first and second toes and a narrow area along the outer border of the foot, is supplied by the superficial peroneal branch of the common peroneal nerve from the fifth lumbar and first sacral segments (fibres from the fourth lumbar and second sacral roots not being represented in the cutaneous distribution of this nerve). The adjacent sides of the first and second toes are supplied by fibres from the deep peroneal branch of the common peroneal nerve from the fifth lumbar and first sacral roots. The outer margin of the dorsum of the foot and little toe receive their cutaneous innervation from the sural nerve, formed by fibres received by communicating branches from both tibial and common peroneal nerves from the fifth lumbar and first sacral segments of the cord. The skin surface over the dorsum of the tips of the toes is supplied by the internal plantar branch of the tibial nerve, the fibres coming from the first sacral root. On the sole of the foot the skin over the heel receives its nerve supply from the medial calcanean branch of the tibial nerve from the first sacral segment. The skin over the medial half of the sole and over the plantar surfaces of the first, second,

third and inner half of the fourth toes is supplied by the medial plantar branch of the tibial nerve, while the integument of the outer half of the sole and over the outer half of the fourth toe, together with the plantar surface of the fifth toe, is innervated by the lateral plantar branch of the tibial nerve, the fibres in both cases coming from the first sacral segment. The posterior aspect of the thigh in its intermediate portion, as well as the posterior aspect of the upper half of the lower leg, receives its cutaneous nerve supply from the posterior femoral cutaneous nerve, the fibres arising from the first, second and third sacral roots.

The importance of these conceptions in the diagnosis of cord lesions and of herpes zoster in reference to the segmental innervation, and in the diagnosis of nerve palsies and peripheral neuritis with regard to the cutaneous nerve supply need only be mentioned here.

' And of those things which are incumbent on the student of this Art (of medicine) are that he should constantly attend the hospitals and sick houses, pay unremitting attention to the conditions and circumstances of their inmates in company with the most acute professors of medicine, and enquire frequently as to the state of the patients and the symptoms apparent in them, bearing in mind what he has read about these variations, and what they indicate of good or evil. If he does this he will reach a high degree in this art. Therefore, it behoves him who desires to be an accomplished physician to follow closely these injunctions, to form his character in accordance with what we have mentioned therein, and not to neglect them. If he does this, his treatment of the sick will be successful, people will have confidence in him and be favourably disposed towards him, and he will win their affection and respect and a good reputation, nor will he lack profit and advantage from them. And God Most High knoweth best.'—*Haly Abbas*

Sir Thomas Browne, the immortal author of *Religio Medici*, said that men could never become physicians from books, but "Galen and Hippocrates must be read as fathers and fountains of the faculty. Lay your foundation in anatomy, read also Vesalius, Spigelius, and Bartholinus, be sure to make yourself master of Dr Harvey's piece *De Circulo Sanguinis*, which discovery is preferable to that of Columbus, study plants, animals, the *materia medicamentorum*, be not a stranger to the useful parts of chemistry, and so by degrees march on. Having learned anatomy, read over two or three times Sennertus's *Institutiones*, after which you will seldom meet with any point in physic on which you will not be able to speak as a man. See how institutes are applicable to practice, but in reading satisfy yourself not so much with the results set down as with the true understanding of the nature of the disease, its causes, and proper indications for cure."—Letter to Dr Henry Power, of Halifax.

THROMBO-ANGIITIS OBLITERANS A PLEA FOR CONSERVATIVE SURGERY

BY GAVIN MILLER, M Sc , M D , AND MARK KAUFMANN, M D

Montreal

THROMBO-ANGIITIS obliterans continues to be a source of great clinical interest, partly because the etiology remains obscure, but even more so because the end results obtained are so unsatisfactory that continuous efforts to open up new therapeutic approaches are being energetically pursued. It was first accurately described and recognized as a clinical entity by Buerger¹ in 1908, since which time he and others have added much knowledge regarding its clinical aspects, its pathology and its treatment.

The symptom-complex occurring in young adults, characterized by the presence of indefinite pains in the foot, in the calf of the leg, or in the toes, and, particularly, a sense of numbness or coldness in unfavourable weather, in fact, a group of symptoms passing through all the phases of ischaemic change up to gangrene, had been known by the name of presenile or spontaneous gangrene.

Two pathological explanations had been advanced. One, the theory of Von Winiwarter, who regarded the process as an endarteritis obliterans in which the closure of the vessels was attributed to a proliferation of the cellular and fibrous elements in the intima, the other, the theory of Von Manteuffel, who attributed the vascular occlusion to a primary arteriosclerosis in which the obliterative process owed its inception to the formation and extension of parietal white thrombi, caused by the desquamation of the endothelial cells lining the vessels. Buerger, by his work, was able to disprove both these theories, but it is remarkable how these former explanations are still advanced in discussions on the pathology of this condition.

The gross pathology, in a well defined case, shows that most of the arteries and veins of the extremity affected are obliterated over a large extent of their course. The primary occlusion is caused by the presence of large, obturating, red thrombi, which show, at times, a well defined upper and lower margin. One of us² has shown, in injected specimens, that these thrombi form patchy irregularities in their distribution throughout the vessel. These thrombi may become

organized and so complete the occluding process, or they may become canalized and vascularized in such a manner as to help in re-establishing the circulation. These changes may be present in various stages in different vessels or in the same vessel. In some cases the veins show much more extensive involvement than the arteries. Another striking feature is the presence of a considerable amount of perivascular inflammation, both arterial and venous. This takes the form of a fibrotic thickening of tissues about the vessels, artery, veins, and frequently the nerve, being bound together in a mass of scar tissue.

The histopathology of the condition has also been well worked out, and to this we owe the thorough understanding of the disease processes. The earliest changes appear to be the usual evidences of an acute inflammatory disturbance affecting all coats of the vessel. The intima, media, adventitia, and perivascular tissues are infiltrated with polymorphonuclear leucocytes, and the lumen of the vessel is completely filled with red clot. Buerger has pointed out that certain peculiar giant-cell foci develop, which are characteristic. These cells may be found either in the vessel wall or in the thrombus in the lumen of the vessel. Their presence represents an intermediate stage in the progress of the inflammatory lesion, they being found as the acute stage is subsiding and chronic productive phenomena are beginning to make their appearance. The next stage shows a series of changes where chronic fibrotic processes control the picture. During this period the thrombus becomes organized and canalized, the evidences of the acute inflammatory disturbances disappear, occupying a minor position in the microscopic picture, and finally fibrous connective tissue is laid down in the vessel walls and in the perivascular tissue.

The above is a description of the pathology of the disease itself. Certain changes, however, are also going on in the affected limb as a result of the interference with the circulation. These changes are in the nature of an effort to establish a collateral circulation. As a vessel is blocked by the disease, attempts are made to furnish

blood to the part deprived of its supply by means of new vessels and channels. A struggle is thus constantly going on in the limb between the advancement of the disease and the attempt to re-establish the circulation. One or the other may gain the upper hand. If the progress of the disease outstrips the collateral vessel development, gangrene occurs. The question of collateral circulation is, therefore, one of great importance and will be discussed more fully later.

The clinical course and history of these cases are, as a rule, straightforward. The patient usually is a young male adult between 25 and 45 years of age, very often of Russian or Polish Jewish stock. The condition, however, is not exclusively confined to Jews. We have seen it in Englishmen, French Canadians, Syrians, and one² of us has reported twenty-five cases seen in China among the Chinese. The condition is fairly widespread in Japan, and sporadic cases have been reported among several other nationalities.

The disease manifests itself in its early stages in different ways. At times the patients will give a history of vague pain, either in the foot or toes. Occasionally, they will complain of a stinging "rheumatic" pain in the region of the tibia and calf of the leg. Others may only be conscious of the foot becoming cold and numb in cold weather, under circumstances in which a healthy foot would not react to the temperature to a similar degree. Again, crampy pains may appear in the muscles of the calf after walking (intermittent claudication). In one case seen by us the only history obtainable was of indefinite pain in the thigh, and yet the disease had progressed sufficiently to obliterate the pulsation in the dorsalis pedis artery. Some patients may give a history of pain and tenderness, with at times redness over many of the superficial veins of the extremity. These areas may show a tendency to disappear and reappear in an irregular manner. The name of migrating thrombophlebitis has been given to this condition, and Buerger considers these changes as almost pathognomonic.

These symptoms outline the preliminary history of the progress of the disease. They may persist for weeks, months or even years, only to be followed by a series of trophic changes resulting in ulceration or gangrene. The earliest manifestation of gangrene may be the development of a hæmorrhagic bleb, a pustule, or a dry dead patch of skin on or near the toes, or on the

heel. The slightest trauma may be sufficient to usher in these changes. Preceding this there is often intense pain, indicating the progress of the vascular obliteration to a point where the gangrenous process might be initiated at any moment.

At any stage with the above mentioned symptoms a new and characteristic sign may make its appearance. This is a peculiar blush of the toes and dorsum of the foot, sometimes extending to the ankle, or slightly above it. It is best shown with the foot in the dependent position. The affected toe is the first to change colour. It becomes a bright red and this gradually diffuses over the area previously indicated. This colour change is called "rubor," or "erythromelia." Associated with this redness, there is a marked increase in the local pain. At this point the disease may rapidly advance to actual gangrene or, adequate collateral circulation developing, the symptoms may subside. Erythromelia is undoubtedly due to a dilatation of the superficial capillaries, probably in response to the anæmia produced by the obliterating vascular processes. It is our opinion that the establishment of rubor marks a critical point in the progress of the disease.

Physical examination at this stage will show, in addition to the rubor and possible ulceration, a loss of pulsation in one or more of the palpable vessels of the extremity. Thus, the dorsalis pedis artery alone may be pulseless, or the lack of pulsation may extend to the tibials, popliteal, femoral, or even to the iliac vessel. The affected limb is of a lower temperature, feeling cold to the palpating hand. It will further be possible to demonstrate a phenomenon which is pathognomonic of organic vascular occlusion. Elevation of both limbs simultaneously will show a marked degree of pallor in the affected limb in comparison to the healthy limb. Depression of both limbs will show a much slower return of the pink colour to the diseased member, this pink gradually deepening into the rubor previously described. The contrast between the two limbs, is, as a rule, marked. We have already stated that the limb may show the reddened, tender, indurated areas along the course of a superficial vein, indicative of the migrating thrombophlebitis, and if the ulcer or gangrenous patch has become infected, a well marked lymphangitis or cellulitis with œdema may be present. Although reference has been made largely to the lower extremity, it must be under-

stood that the vessels of the upper extremity may also be affected

Recent work has been carried out with the Pachon oscillogram. This instrument records a smaller range of oscillation in the affected than in the normal limb.³

We have already referred to the progress of the disease as a struggle going on between obliteration of vessels and re-establishment of new channels. We believe a thorough understanding of this feature of the disease to be essential. Its course is not one of a smooth uninterrupted progression. We feel that characteristic of the condition is a series of exacerbations and remissions. With each exacerbation more and more vessels are obliterated. The disease advances proximally. The subsidence of the symptoms produced by the vascular obliteration would indicate that enough collaterals have been opened up, thus preventing the anæmia from progressing to the stage of gangrene. So it will be seen that the progress of the disease is uneven and that this struggle may go on for a number of years, until finally the disease is arrested, or gangrene supervenes.

It is evident that any rational therapeutic approach must consider two factors. First, the removal of the cause, and, secondly, the development of the collateral circulation, so that the impending gangrene may be averted. In regard to the first factor the etiology of the disease remains obscure. Many theories have been advanced, all have been found wanting.

The suggestions of excessive smoking,⁴ exposure, the increase in the viscosity of the blood,⁵ the use of food containing vaso-constrictors,⁶ such as rye fungus, alterations in blood chemistry⁷ and changes in hæmatological findings,⁸ endocrine disturbance,⁹ and finally the bacteriology of the disease,¹⁰ have all received their share of attention, but have failed to find confirmation. The work of Rabinowitz is worthy of comment in view of the recent revival of theory of the specificity of micro-organisms in various diseases. We are, however, faced with the striking lack of confirmation of this work. The lesion undoubtedly appears to be of an inflammatory nature and further work along bacteriological lines would be of interest.

Supporters of these various theories of the cause of the disease have advanced methods of treatment intended to act upon the respective etiological factors, so that dietary restriction, organotherapy, intravenous use of solutions to

diminish viscosity of the blood have all played their part in the therapy of this disease. The majority have failed to survive a thorough test. We are consequently faced with the necessity of evolving measures to promote the establishment of an efficient collateral circulation, realizing that the impending gangrene could be prevented and the co-incident pain relieved by supplying blood to the ischaemic areas. Those cases that show spontaneous arrest of the disease over periods varying from one to several years have been shown to have established a well developed collateral circulation. Therapeutic measures along these lines can do no better than to imitate Nature's method.

These measures may be divided into two groups. First, those which aim, by some mechanical measure, to produce rapidly an efficient collateral circulation. An example of this type is the ligation of the femoral artery, as advocated by Lewis and Reichert.¹¹ Secondly, those which aim at the relief of pain. Pain is the symptom which will most often serve as the indication for operative interference. Relieve the pain and the natural tendency towards the formation of a collateral circulation will be allowed to proceed without interruption. In discussing the first group, mention might be made of the operations formerly attempted with the object of increasing the blood supply to the anæmic area. These are the operations of ligation of the femoral vein¹² and arteriovenous anastomosis.¹³ Both of these, however, were based upon an improper understanding of the pathology of the disease, and naturally found no place in its treatment.

The work of Lewis and Reichert¹¹ was the first rational attempt to surgically assist the compensatory mechanism of collateral circulation to develop. We feel, however, inclined to doubt the efficiency of ligation of the femoral artery. In the irregular progress of the disease one attack of arterial obstruction follows on another each attack presumably obliterating a portion of the vessel at a little higher level. This corresponds then to repeated ligation of the artery. It is difficult to see how ligation of the vessel at one spot will do more than what amounts to repeated ligation, as evidenced in the progress of the disease. It is apparent, too, that Lewis' operation is applicable only to those cases in which the femoral artery in Scarpa's triangle is patent. This would naturally limit the scope of the operation. We have so frequently found the femoral artery obliterated in its whole course that

we look upon those cases as the exception rather than the rule. It is possible that Lewis and Reichert based their operations on the conclusions of Halstead,¹⁴ namely, that the higher the ligation the greater the possibility of a sufficient collateral circulation being established. Halstead's work, however, was based upon experiments where the vasculature distal to the point of ligature was a healthy one. In Buerger's disease the opposite obtains. The vessels distal to the ligature are in the majority of instances thrombosed and obliterated.

We have, however, to account for the fact that improvement has followed on Lewis' operations just as improvement has been reported to follow other operations designed to alleviate this condition. How can we explain these results? We know that the advance of the disease, each new extension of the obliterating process, deprives the extremity of blood, thereby producing great pain. As a rule, at this stage, the patient will present himself for treatment. We know that coincident with the occlusion collateral circulation begins to be established. Irrespective of any operative procedure, the process of collateral establishment will proceed as rapidly as it can. We feel, therefore, that the majority of these measures, regardless of their rationale, act only by relieving pain, and in no way tend to mechanically assist in collateral development. We cannot attempt, at present, to fully explain the relief of pain brought about by periarterial sympathectomy, ligation of the femoral vessels, intravenous injections of hypertonic saline, foreign protein therapy, etc., but we feel that in this relief lies the true value of their action.

Based upon our understanding of the disease, as explained in the foregoing paragraphs, we feel that conservatism should be the keynote in the treatment of this condition. It is only a very few years ago since high amputation was considered the treatment of choice, irrespective of the extent of the gangrene. It is interesting to see how gradually the surgical mind as regards this radical procedure has undergone a change. In a personal communication to one of us, Silbert of the Mount Sinai Hospital of New York City stated that he had reduced the percentage of cases coming to amputation from 70 per cent to 12 per cent by means of conservative treatment. The figures from the department of surgery of the Royal Victoria Hospital show that during the last ten years a total of nineteen cases were admitted suffering from thrombo-angitis ob-

literans. Of these nineteen admissions the last five were treated along purely conservative lines. Of these five only one up to the time of writing has required amputation, and that on account of the presence of a fairly extensive gangrenous area developing on the dorsum of the foot. Of the fourteen cases treated prior to the last five admissions, and before the adoption of prolonged conservative treatment, eleven, or 79 per cent, underwent amputation, eight requiring bilateral amputation. These striking figures illustrate well the possibilities that can be obtained by treating these patients by the most conservative means available.*

We have already made brief mention of certain measures which have been tried in this condition with apparently good results. From our own experience, and from an extensive study of the results obtained by others the following mode of procedure is suggested—

- 1 Rest

- 2 Dietary restriction and absolute restriction of tobacco. The belief is prevalent in the larger clinics that tobacco smoking as an etiological factor is not to be minimised.

- 3 *Buerger's exercises*. These exercises tend to mechanically improve circulation in the affected extremity. They consist of elevation of the leg for the minimum amount of time necessary to produce ischaemia (30 seconds to 3 minutes). The leg is then put down over the edge of the bed and kept there for one minute after the maximum red colour has been produced (2-5 minutes). The leg is then placed in the horizontal position for from three to five minutes, during which time dry heat is applied. This group of movements is repeated during an hour and every alternate hour is taken up in this way. During the rest period dry heat is applied continuously. It is very difficult to obtain a patient's co-operation for the proper carrying out of these exercises on account of their tediousness. A cycle of these movements every third hour will probably be of some benefit, without unduly taxing the patient.

- 4 Intravenous injection of hypertonic saline. It has been found in some clinics that 300 c c of

* Since writing the above it has been necessary to amputate an extremity of one of the patients, who had been treated by conservative means. It is noteworthy that this patient had refused to stop smoking or, to come regularly for treatment. The oscillometer readings in this case were very low and periarterial sympathectomy had been tried in an effort to relieve the pain without result. The femoral artery was shown to be obliterated at this operation.

5 per cent saline, injected intravenously, will help to relieve pain. This is given three times a week until definite relief occurs.

5 Allen and Browne¹⁵ have produced increased warmth in the extremity with relief of pain by the use of typhoid vaccine in sufficient quantities to produce a sharp general reaction.

6 During the acute period when pain fails to be relieved by any of the above procedures, or by the use of the ordinary drugs, (morphine, aspirin, codeine, veronal, etc.) periarterial sympathectomy may be attempted. Good results have also been reported following lumbar ganglionectomy. We do not feel that much benefit can be expected from these procedures.

7 Frequently, when the condition is improving and the pain has subsided, we are left with a patch of gangrene affecting one of the toes. This can be locally excised or the toe amputated. Healing will rarely take place by first intention but the wound will slowly granulate and eventually cicatrize.

SUMMARY

Thrombo-angitis obliterans partakes of all the phenomena of an inflammatory disease affecting blood vessels, nerves, and perivascular tissues of the extremities. Its progress is charac-

terized by a series of exacerbations and remissions of varying length and varying result. Relief of the condition will depend upon the establishment of an efficient collateral circulation. Conservative measures of treatment will tend to permit the establishment of this collateral circulation. By use of these measures high amputation will be necessary in a much smaller number of cases.

ETHYLENE ANÆSTHESIA*

By EDITH ROSS, M D,

Chief Anæsthetist to St Boniface Hospital,

Winnipeg

THERE is nothing new in the idea of using ethylene as a general anæsthetic. Twenty years ago Luckhardt, to whose work, chiefly, we owe this agent, began animal experiments with it, proving it to be non-toxic, analgesic and anæsthetic. At that point the work was dropped, but early in 1923 attention was again drawn to ethylene by Easson Brown in Toronto, and by Luckhardt and Carter in Chicago.

Brown, whose attention had been attracted to ethylene by the statement that it was one of the impurities in a commercial ether, read a paper in Toronto, describing some animal experiments

with ethylene, which paper was published in the *Canadian Medical Association Journal*†

About the same time, Luckhardt's work had progressed to the point where he and Carter arranged a demonstration of ethylene anæsthesia on laboratory animals, and on some volunteers, before a group of Chicago surgeons and anæsthetists, and a few days later on March 14 1923, ethylene as an anæsthetic for a surgical operation was given for the first time by Dr Isabella Herb in the Presbyterian Hospital there.

The anæsthetists at the Presbyterian Hospital have always been strongly opposed to the use of premedication, and consequently were even more handicapped by the shortcomings of nitrous

* Read before the Winnipeg Medical Society, May 4, 1928

† March, 1923, *cm*, 210

oxide than others were. This probably accounted in some measure for the very enthusiastic reception accorded this new agent, both by anæsthetists and surgeons there.

Six or seven months later, at the International Congress of Anæsthetists in Chicago, ethylene was the centre of interest, and certainly the most talked-of subject, but at that time the general opinion seemed to be that methods of manufacture were not sufficiently standardized, and that ethylene anæsthesia was still more or less in the experimental stage. Since that time methods of manufacture and technique have progressed until now the use of ethylene has spread to every clinic and hospital of importance in the United States, and to many hospitals in Canada, and it can be said to be as definitely established as any other anæsthetic agent.

The method of manufacture is of little interest to us, but some of its physical characteristics are worthy of attention. It is a gas at ordinary temperatures and pressures, but is stored in liquid form in tanks, as nitrous oxide is, under considerable pressure. It is, like ether, highly soluble in fats, a lipid solvent. Its boiling point is -157°F , lower than nitrous oxide which is -137°F . Ethylene is very rapidly eliminated on account of its low boiling point, although its affinity for fats makes its elimination somewhat slower than nitrous oxide with its somewhat higher boiling point. It seems to exist in the blood merely in a state of solution, apparently not combining with the hæmoglobin.

Ethylene, speaking generally, occupies a place in the scale of anæsthetic potency about midway between nitrous oxide and ether, partaking to some extent both of their advantages and disadvantages but bridging what was previously a rather awkward gap between them.

To begin with the disadvantages. One cannot help mentioning the odour, because it is the first thing to attract attention. It has been described by almost everyone as unpleasant, but perhaps the most striking thing about it is the ease with which one becomes accustomed to it. So far as patients are concerned, I have never heard one complain of the odour. One may induce anæsthesia with nitrous oxide if desired, but, in any case, induction with ethylene is so rapid that one or two breaths are all the patient will notice. The other and the only serious objection to ethylene is its explosive character. This is a very real danger, and definitely rules

out the use of ethylene in cases where cautery or flame of any sort may be present or used. It is also impossible to use ethylene in the presence of diathermy apparatus, x-ray machines, and other electrical apparatus from which sparks may be given out. There is also danger from static sparks. At the same time, while unfailing caution must be exercised, one should realize that the danger of explosion is within certain definite limits, and is really probably no greater than with ether vapour. In this connection we may remember that the combustible range for ether vapour, as given by the Bureau of Explosives, lies within the limits ordinarily used in anæsthesia, while that for ethylene lies far below the mixtures required for narcosis. A good many of the explosions reported, and there are not many after all, have occurred when the apparatus was not in use, from ethylene left in the breathing-tube and mask, and they could have been prevented by shutting the ethylene tank valve, exhausting all the ethylene in the machine, and flushing the tube and mask with nitrous oxide before finishing the anæsthetic.

Ethylene itself, in the cylinder, and until it has been mixed with oxygen, cannot explode. Mixtures in common use contain from 10 per cent to 25 per cent oxygen, and Easson Brown has determined experimentally that the minimum amount of oxygen necessary for a mixture to explode was from 40 to 45 per cent, mixtures from this percentage up giving increasingly violent explosions. It is almost out of the question for escaped ethylene to reach explosive proportions in the air of an operating room. It has been estimated that it would require six hours of continuous anæsthesia, with no ventilation, for the atmosphere to reach the required percentage. McKesson thinks that ethylene is probably less explosive than ether vapour under ordinary operating conditions.

The general opinion is that if reasonable care is taken and is *always* taken, ethylene is as safe as ether, so far as explosion is concerned. This does not mean, however, that one can ever relax his vigilance. It is the easiest thing in the world to drop into the familiarity which breeds contempt, and one must draw a definite, hard-and-fast line in connection with the use of ethylene.

The advantages of ethylene are many. As stated before, induction is very rapid, and not unpleasant. There is practically never the excitement that one occasionally sees with

nitrous oxide, which has gained for that anæsthetic agent the term "laughing gas." The ease and rapidity of induction with ethylene are of special value in dealing with alcoholics, drug addicts, and other extremely nervous people.

The relaxation obtained with ethylene is one of its marked advantages over nitrous oxide, though it falls short of ether in that respect. It resembles ether in that the relaxation is not obtained immediately, but approaches its maximum only after ten minutes or longer, and for this reason, in cases requiring relaxation, the anæsthetic should be begun as early as if one were using ether. We have found ethylene so much superior to nitrous oxide in this respect that it has eliminated almost entirely the need for adding ether to gas anæsthetics in the case of laparotomies. The relaxation which can be obtained is such that it has been found possible to repair a perforated duodenal ulcer under pure ethylene-oxygen anæsthesia. You will realize that this implies both relaxation from the anæsthetic, and co-operation from the surgeon. As a matter of fact, it is never possible to use gas-oxygen anæsthesia without this latter factor.

The colour under ethylene differs greatly from the dusky, often cyanotic, hue under nitrous oxide. It is usually a bright rosy pink, accounted for to some extent by the increased oxygen percentage permissible with ethylene, over that possible with nitrous oxide, but it has been suggested that it is due to a lowered tissue metabolism under ethylene, in which less oxygen is drawn from the blood. If that is true it may be a factor in its evident advantage in toxic goitres.

In the matter of blood pressures there is some difference of opinion, but most anæsthetists agree that there are no changes in readings, under surgical anæsthesia, in normal patients, *if the element of asphyxia is eliminated.* The following statements may be quoted:

"As ethylene is known to have little effect on the blood pressure it is well suited for the cardio-vascular, nephritic and diabetic patient" (Donald Guthrie).

"In the absence of hæmorrhage there is little change in blood pressure, whereas in cases of hypertension the tendency to a reduction is usually well-marked" (Hastrieter).

"The blood pressure is lowered in deep anæsthesia, unchanged in others. The pulse and

blood pressure are influenced less by ethylene than by any other agent" (Christiansen).

"It is without marked effect on ordinary blood pressure. In chronic hypertension pressures may drop almost to normal level under ethylene without danger, provided the pulse rate decreases also."

It has been stated by some observers that there is an increased oozing from superficial tissues. Others deny this, and have reported several series of cases in which the bleeding time and coagulation-time were taken before, during, and after ethylene anæsthesia, and practically all report that both are decreased during anæsthesia. This condition usually becomes more marked following anæsthesia, and persists until the following day when the times become normal. This was especially noted in a series of jaundiced patients and should it prove true, is a most important observation.

There is no pulmonary irritation with ethylene. It may be given with safety in acute respiratory conditions, and is especially valuable in some of these, as for instance, in acute abdominal conditions, with pneumonia, where nitrous oxide is usually insufficient without the addition of some ether. Ethylene has been given in many thousands of tuberculous patients for varied procedures with no lighting up of quiescent lesions or aggravation of active ones.

There is no effect on the kidneys, and ethylene may therefore be used for nephritis as safely as nitrous oxide. It is said that ethylene is the only agent which does not decrease the CO_2 combining power of the blood, and that it in fact increases it, which should increase its use in diabetics.

The heart action does not seem to be affected by ethylene, and the slower respiratory rates, with their accompanying slower pulse rates, must be beneficial to patients suffering from heart lesions.

It is said that ethylene produces less post-operative shock, both immediate and remote, less headache than that frequently following nitrous oxide, less vomiting, nausea and general discomfort than following ether, though somewhat more than that following nitrous oxide. Gas-pains have been said to be less than after ether and chloroform anæsthesia. Patients with low hæmoglobin percentages do well on ethylene, better than on nitrous oxide because of the larger percentage of oxygen given. In fact, we

have a decided impression that the larger amount of oxygen is responsible for most of the benefits, since we believe that the element of relative asphyxia is responsible for many of the post-anæsthetic discomforts and dangers.

Sweating is usually noticeable under ethylene by its absence, the skin being warm and dry, and this is a decided advantage in the dehydrated patient. It is astonishing how much fluid the sweating patient can lose in the course of an hour or more.

Experimentally, on isolated uterine muscle, ethylene is the only anæsthetic which does not show an inhibiting effect on contractions. Whether or not this holds good in obstetrical practice I do not know, but ethylene appears to have no deleterious effect on mother or child. My experience with it in obstetrics is too small to base upon it any opinion as to its relative value.

Surgical anæsthesia from ethylene presents a patient whose condition more closely approaches the normal than is the case with any other anæsthetic agent, with rosy colour, slow regular respirations, slow, regular, full, pulse, no mucous or salivary secretion, usually good relaxation, and a warm, dry skin. Recovery from the anæsthesia is rapid, though vomiting is somewhat more common than with nitrous oxide. Recovery is not quite so sudden and complete as it is with nitrous oxide, where the patient is sufficiently conscious to appreciate a good deal of the more acute pain of his wound. Ethylene appears to leave a persisting analgesia behind it, which makes people somewhat more comfortable. Convalescence is definitely shortened with ethylene, as with nitrous oxide, these two gases usually shorten the hospital stay of patients by a day or two.

With all this information available for some time, the curious thing is, not that ethylene anæsthesia was introduced into St Boniface Hospital in January of last year, but that none of us had done it long before. When we spoke of buying a McKesson gas machine a year earlier, we suggested to Dr Fahrni, the chief of our surgical staff, that we might get one with an ethylene attachment. With his encouragement, we did. But later, when we decided to try ethylene, we had quite unexpected difficulty in getting any to try. One firm assured us that the railroads and express companies in Canada would not carry ethylene, and, that they them-

selves were decidedly not interested in handling it. The trouble was mentioned to Mr Martin, then of the Surgical Supply Company, and a tank of ethylene was delivered in short order, and there has been no further trouble in obtaining it.

After fifteen or sixteen months' experience, our ideas about ethylene have become more or less crystallized. We usually induce anæsthesia with nitrous oxide-oxygen, but find straight ethylene-oxygen very valuable in alcoholics, and all highly nervous people. Probably it is as good a routine as to induce with nitrous oxide, but we feel that we have more or less accidentally avoided some of the dangers of explosion by this method, as we have been careful to flush out all ethylene from the machine before leaving it. This leaves it free from odour for the next patient, and also obviates to some extent the danger of explosion from static sparks when the machine is idle.

We think ethylene is definitely indicated in the extremes of life (it has been used in patients from three days to eighty-four years old), in septic cases of all kinds, and in anæmic patients. We think that almost all laparotomies in which it is proposed to use gas-oxygen, either on account of some definite indication or from preference, are better done under ethylene than under nitrous oxide. But the type of case in which we think ethylene is really invaluable is in the toxic goitres. Here are people who are really short of oxygen when they are breathing air with its 20 per cent content. Imagine how they find themselves, breathing an anæsthetic mixture of nitrous oxide and 10 to 15 per cent of oxygen, which is the average amount permissible, even with the additional help of novocain. Within a very few minutes these patients present a very unpleasant picture. The relative anoxæmia under their greatly increased oxygen requirements, results in a greatly increased respiratory rate, the pulse following the respiratory lead, the patient is perspiring and cyanotic, and the anæsthetist feels much more miserable than most of you even imagine. Think, too, of the purely physical exhaustion induced by breathing forty or fifty times a minute, for forty minutes or an hour or even more, then think of the strain on a heart which is trying to keep up with a situation like that. Imagine watching patients like that for years, wondering what one could do to change the

picture, and then some morning turning a valve and altering the entire appearance in the space of three or four breaths. It is hardly possible to understand how sudden and how gratifying this change is without seeing it. On one occasion, for instance, the machine with the ethylene was not available for ten minutes or more after I anesthetized with nitrous oxide a fairly sick exophthalmic goitre patient, and during this ten or twelve minutes under nitrous oxide oxygen, even with the oxygen pushed to the point of very light anesthesia, the respiratory rate quickly reached 48 per minute, with the pulse racing along trying to keep pace with it, at 140. When the switch to ethylene was made, the second breath sounded so different that the surgeon said, having had experience with this before, "What has happened, has the ethylene come?" Beginning with the third respiration under ethylene the respiratory rate was 28, and later dropped to 24. The respirations gave one an impression which cannot be described better than by saying that it sounded as though they satisfied the patient. The pulse quickly followed suit, dropping to 120, then to 110, staying between that and 100 for the rest of the operation. This change was so marked and so constant in our earlier goitres under ethylene that we now either carry them through entirely under ethylene-oxygen, or turn to that, after starting them with nitrous-oxide, as soon as unconsciousness is attained. Our habit of flushing out ethylene with nitrous oxide just before the end of an operation is perhaps not good practice in these people, for one often sees them "steam up" again, even with these few breaths of nitrous oxide, but it is in the interests of safety.

We are very decidedly of the opinion that ethylene is the anæsthetic of choice for goitres

which have any degree of toxicity. It has been possible to carry practically all our goitre cases with 20 per cent oxygen, and in many, particularly of the more toxic ones, the percentage can be increased to 25, 30, or even 35 per cent, with satisfactory anæsthesia. The reflex spasms which fairly often occur in goitre work, and which should be merely momentary embarrassments under light anæsthesia, often develop into very unpleasant situations when the patient is under deeper anæsthesia. This light anæsthesia, so important in the cases in which the trachea is often distorted or compressed to some extent by manipulation, and in which the nerves may be irritated indirectly by traction or pressure, even though they may never be directly irritated, is much more easily and more evenly maintained with ethylene than is a similar stage under nitrous oxide.

We have, in fact, almost arrived at the point where we feel that any case for which nitrous oxide is advisable will do better under ethylene, and we have quite arrived at the point where we must say that the range of gas-oxygen anæsthesia has been extended to include numerous patients who were formerly outside it.

It is a great satisfaction now to know that, while Dr. Richardson, formerly senior interne in St. Boniface Hospital, introduced the use of ethylene, and nitrous oxide as well, in Brandon, nearly a year ago, the use of ethylene is becoming more general in Winnipeg.

We would like to take this opportunity of expressing our great appreciation of the hearty co-operation and support which the surgical staff particularly, and many visiting surgeons, also, at St. Boniface Hospital, have given us in this matter.

A case of functional aphasia—"The celebrated St. John of Beverley, being accustomed at the beginning of Lent to seek out some specially sick or poor person to whom he might do good, found a boy who was completely dumb, so that when he came to the bishop to receive alms he could not speak a single word. He was, however, as appears, not deaf. Besides this, he had so much scurf and scab on his head that no hair would ever grow there, but only some bristly locks were seen standing round about it. The bishop provided a lodging for the youth near his own house, and on a certain day called him before him, and making the sign of the cross on the

dumb boy's tongue said, 'Pronounce some word, say Gae (yea)'. The boy immediately said what he was ordered. The bishop then added the names of letters 'Say A'. He said A. 'Say B,' and he said this also. And when he said after the bishop the names of the letters, the latter proceeded to put syllables and words for him to say. And when he had repeated all these properly, he desired him to say whole sentences, and he did so, and went on talking the whole of that day and part of the night, so that he was completely cured."—Dr. Payne, Fitzpatrick Lectures, 1903.

Case Reports

DOUBLE FRACTURE OF THE MANDIBLE PREDISPOSED BY AN IMPACTED THIRD MOLAR

By DR W AUBREY CRICH,

Dental Department, Lockwood Clinic,

Toronto

Mr F, aged 22 years, came to the Lockwood Clinic on January 30, 1928, on account of pain and swelling at the angle of the jaw on the left side and inability to use his lower jaw

History—On the afternoon of January 21st, he had been boxing and had received a heavy blow on the left side of his chin. This blow had lifted him off his feet, had dazed him a little, but had not terminated the bout. His mouth had bled, and he had spat considerable blood. He experienced difficulty eating that night, but was able to move his lower jaw sufficiently to eat soft food. The jaw became more painful during the night and began to swell at the angle on the left side. Pain was not severe at any time, but the lower jaw became stiff and after a day or two he found that he could not use it, neither could he bring his anterior teeth together. Several days later a painful swelling appeared in the bicuspid area on the right side of the mandible. This drained and the pain disappeared.

Examination—The patient was a well-nourished individual. He had considerable swelling at the angle of his lower jaw on the left side, and could not open his mouth on account of trismus of the muscles of mastication. The anterior teeth were not in occlusion, the greatest amount of separation being in the region of the first bicuspid on the lower right side. The lower posterior teeth were fairly well up in occlusion. On manipulation, definite movement of the mandible could be seen between the lower right bicuspid teeth. Pain in this area, and also in the area of the angle on the opposite side, was increased by the slightest movement of the mandible. The lower right first bicuspid tooth was slightly loose. There were no areas of anaesthesia present, therefore no injury to the inferior dental nerves, nor any ecchymosis. It was difficult to obtain a good view of the lower left molar area, but the third molar was seen to be missing. There was no break in the mucous membrane in this area.

Diagnosis—With these clinical signs, a diagnosis was made of double fracture of the mandible, compound on the right side, and probably simple on the left side. Extra and intra-oral x-rays confirmed the diagnosis. The fracture at the angle was seen to be complicated by an impacted third molar which was lying in a horizontal position, with its crown lying in the line of

FIG 1—An x ray showing an impacted third molar lying in the line of fracture. The injury was the result of a blow received on the left side of the jaw during a boxing bout.

FIG 2—An x ray showing the fracture just distal to the second bicuspid which occurred on the opposite side in the case described in Fig 1

fracture. The x-ray showed that there was little displacement in this area. The line of fracture on the right side was shown just distal to the first bicuspid and extended down through the socket of this tooth. Reduction of the fractures was advised after the removal of the lower right first bicuspid tooth.

TREATMENT

The lower right first bicuspid was removed under local anaesthesia. The occlusion was studied and it was seen, from the abrasion of the incisal edges of the central and lateral incisors, that the patient's teeth had not been in perfect occlusion. This was interesting, as the most certain guide for restoration of the fragments to their normal position is the restoration and main-

tenance of the teeth in their normal occlusion Gilmer's "modified method" of wiring the lower teeth to the teeth of the upper jaw was the method of choice. Fixation of the splints and reduction of the fractures is most satisfactorily accomplished under the influence of $\frac{1}{2}$ gr of morphine sulphate and 1/150 gr of scopolamine

FIG 3—Gilmer's modified method of wiring the lower teeth to the teeth of the upper arch in a fracture of the mandible

FIG 4—Side view showing the method used in wiring the lower teeth to the teeth of the upper arch in a fracture of the mandible

On February 1st, splints in the form of arch wires of fourteen gauge German silver wire were made to conform to the buccal surfaces of the teeth in the upper and lower arches, extending from the first molar on the left side to the corresponding tooth on the opposite side. The arch wires were annealed, polished, and sterilized before being used. The ends of the upper arch wire were bent downward to make a small loop in order to lessen irritation of the tissues, while the ends of the lower arch wire were looped upwards. Twenty-five gauge German silver wire was used as "interlacing wire," to fix the arch wire to the teeth. The arch wire was fixed to each tooth in the upper arch, from the first molar on the left side around to the corresponding molar on the opposite side. The interlacing wires were passed between the teeth above the contact points, one end being brought out below the arch wire, the other end above it. The ends of the

wires were then twisted together and a pair of hæmostatic forceps was used to tighten these, care being taken to draw the ends of the wires away from the tooth, thus avoiding breakage. Final tightening of the wires was not done until all the wires were in position. A small pair of curved hæmostatic forceps was used to guide the ends of the interlacing wires through the interproximal spaces. The ends of the twisted wires were cut rather short, and then bent to form a small loop, the end being tucked under the arch wire. The lower arch wire was fixed to the lower teeth in a similar manner, the wires passing through the interproximal spaces below the contact points.

Double thicknesses of interlacing wires were used as reduction wires. The reduction wires were passed under the arch wires in chosen positions, so that when force and tension were exerted upon them the teeth would be brought up into their proper occlusion and the fractures reduced. (All the reduction wires should be in position before final reduction is made.) On tightening the reducing wires, the teeth came into occlusion. The ends of these wires were carefully bent, in order to prevent irritation.

The patient was advised to keep his mouth as clean as possible. A 50 per cent solution of stock hydrogen peroxide is a good mouth wash. A small tooth-brush may be used to good advantage, to prevent the collection of debris about the wires. Pledgets of cotton saturated with hydrogen peroxide should be rubbed over the teeth and mucous membranes twice daily in such a case.

The lower cuspids being conical in shape, the interlacing wires on these teeth became loose in the course of a day or two and were removed. The removal of these wires did not affect the stability of the lower arch wire. Five days following reduction the patient experienced more swelling, accompanied by pain at the angle on the left side. He was advised to apply hot moist compresses over this area and to use a warm mouth wash. The swelling was greatly reduced by the following day. On February 18th the reduction wires were cut and the case studied. The patient was able to open his mouth about one half inch after practising a few minutes. Gentle massage was given to the fractured areas. Some of the interlacing wires were tightened and the reduction wires again replaced. On February 28th the splints were removed, and the patient was cautioned against using his jaw too vigor-

ously Following removal of the splints, more swelling appeared at the angle of the jaw and the glands in the side of the neck felt hard on palpation. A small quantity of pus could be expressed from the gingival crevice, just anterior to the second molar. Hot moist compresses were applied to this area until fluctuation could be detected, and then extra-oral drainage was obtained. The wound drained for six days and then healed. Since that time the jaw has been functioning normally and the patient has had no discomfort.

DISCUSSION

This case is particularly interesting on account of the impacted lower left third molar. Local predisposing causes of fracture of the mandible are usually tumours of bone, such as sarcoma or carcinoma, or, even more often, cysts, osteomyelitis, or gumma, but in this case it was an impacted molar.

Before attempting reduction here, one had to decide what should be done with regard to this impacted tooth. The common rule is to remove teeth in the line of fracture. In order to remove this tooth some of the bony tissue overlying the tooth would have had to be removed. This would have meant weakening the short fragment, and would also have caused considerable trauma to the tissues. This tooth could not have been removed without getting more infection into the wound, which would have interfered with healing. If the roots of the impaction had been lying in the line of fracture, the shock would possibly have caused the nerve of the tooth to die, and the tooth would then have had to be removed. Loose teeth or roots in the line of fracture should always be removed. (Removal of this impacted tooth has been advised and will be done about six months later.)

Nearly all fractures of the jaw are compound, hence usually become infected. Hot moist compresses applied to the outside tend to combat the infection or cause it to localize. The abscess should be opened as soon as fluctuation can be detected. This is most satisfactorily accomplished under nitrous-oxide anaesthesia. A general anaesthetic should never be given with the reduction wires in position. A small incision should be made in the skin, and then a blunt dissection down to the periosteum made with a pair of scissors. A few thicknesses of sterile rubber tissue placed in the wound will insure good drainage. Although the fracture at the angle in

this case was thought to be "simple," it no doubt became infected by seepage of saliva into it by way of the gingival crevice around the second molar. A culture taken from around the crown of an unerupted tooth, such as this, always shows the presence of a mixed type of infection. Slight swelling usually persists in these areas for a few months, and it is advisable to inform the patient of this fact.

Anyone who has not seen fractures treated by this modified method of Gulmer's might think that the interlacing wires would cause considerable trauma to the gingival tissue. This is not the case, and it is surprising to see how little irritation the wires cause. When the reduction wires are tightened, they tend to draw the arch wires toward the occlusal surfaces of the teeth and hence the interlacing wires away from the gingiva. If the ends of the wires are carefully bent and tucked under the arch wires, the lips and buccal membranes will not be irritated. If one is afraid of this, dental compound may be used to round over these ends.

Whenever there are a few sound teeth in the opposing jaws, this method, in my estimation, is the most satisfactory. These splints are easily placed in position, whereas the patient is caused much discomfort in taking impressions in order to make either swaged or cast splints. With this method of wiring it is possible to study the occlusion of the teeth at all times, as there is no thickness of metal between the upper and lower teeth. The method also saves the patient money, and, as most fractures of the jaw occur in the poorer classes, this fact should be taken into consideration. In cases of nausea or sickness the reduction wires may be easily cut, the mouth opened and again reduced. If one or two interlacing wires should break, they may be ignored, whereas with other methods of wiring they must be replaced.

About 1 per cent of all fractures recorded are of the mandible, while about 0.5 per cent are of the maxilla. This case is a common type of fracture, as the point of impact of the breaking force was situated midway between the two points of fracture. When there is a fracture at the angle, the break is usually anterior from below upward, and at an angle of about 60°. The mandible is almost as frequently fractured in two places as in one place only, the fractures usually occurring on opposite sides. Fracture of the mandible most frequently occurs in the mental region. The bone in this area is weakened to a certain extent by the mental foramen and also

by the peculiarly attenuated internal structure of the bone at this point. This position is also the middle of the curve in the body of the jaw. Other common sites are (1) the angle of the jaw, (2) between the angle and mental foramen, (3) symphysis menti, (4) ramus, (5) condyloid process, (6) coronoid process.

It is never necessary to extract, to provide space for the passage of food in the case of a patient wearing interdental splints or where the upper and lower teeth are wired together. Fluids and soft foods may always be taken either through places where teeth have previously been lost or behind the last molar. On the day following reduction, this patient reported that he could take fluids, and that he had no trouble in taking cream of wheat, mashed potatoes, ice cream, etc. He was able to talk and had no difficulty making himself understood, and was only away from his work for a few days. These patients usually lose a few pounds of weight the first few days after reduction, but ordinarily regain it within a week or two.

There is usually little difficulty in making a diagnosis of fracture of the mandible, but this is greatly facilitated when there are considerable teeth present, as malocclusion is one of the best clinical signs. Extra-oral skiagrams should always be taken of both sides of the mandible, as frequently with a fracture of the body of the mandible one finds a fracture of the neck of the condyle on the opposite side.

Union in healthy patients should occur between thirty and forty days and always more promptly when the fragments are brought into proper juxtaposition and so retained.

TWO CASES OF HYPERVENTILATION TETANY

BY J. R. MONTEITH, M.D.

Demonstrator in Medicine

AND A. T. CAMLON, D.Sc., F.R.S.C.

*Professor of Biochemistry, University
of Manitoba*

Winnipeg

In 1920 Collip and Baekus in Canada,¹ and Grant and Goldman² in the United States, described the experimental production of a tetany in normal man by prolonged forced breathing. Since that time this type of tetany has been thoroughly studied and there is practically

unanimity of agreement that it is associated with an alkalosis, traceable to the excessive lung ventilation and resulting depletion of carbon dioxide from the alveolar air and from the blood. Blood calcium, instead of being below normal as in the tetany of parathyroid deficiency, is either normal or slightly increased.^{2, 3, 4, 5}

Such a "hyperventilation" tetany, occurring under clinical conditions has been but seldom reported. The few cases in the literature each present their own peculiar features. It seems desirable to report every recognized case until such time as the possible variations in the causative agencies of this particular type of tetany are fully realized.

Barker and Sprunt's case,⁶ the first reported, is summarized in its title "A spontaneous attack of tetany during a paroxysm of hyperpnœa in a psycho-neurotic patient convalescent from epidemic encephalitis." Goldman⁷ described four cases in which definite manifestations of tetany were present, and two others which showed suggestive symptoms. The increased respiration in these four cases was associated with, respectively, cholelithiasis and cholecystitis, exercise following nausea due to indigestion, a neurosis associated with crying spells, and influenza followed by abdominal symptoms of questionable origin. Goldman also mentions the occurrence of definite symptoms in five college students following a class fight, these students were in poor physical condition. Pagniez, Lerond, and Lebel⁸ report a case of tetany following retention of urine, due to irritation, which set up prolonged groaning, following administration of morphine for a previous gonorrhœa.

In all these cases the actual tetanic manifestations were preceded by a definite and prolonged hyperpnœa. The causes leading to this hyperpnœa varied. With these clinical cases can be perhaps closely compared the experimental production of tetany through hyperpnœa following prolonged immersion in hot baths, as in the experiments reported by Landis, Long, Dunn, Jackson, and Meyer.⁹

In this paper two more clinical cases are reported, the first a patient of Dr. Charles Hunter, Professor of Medicine, and the second a patient of Dr. A. J. Burridge, Associate Professor of Clinical Medicine in this University. To both Dr. Hunter and Dr. Burridge we tender our thanks for permission to publish these records.

CASE 1

Mrs P, aged 32, was admitted to the Winnipeg General Hospital on January 20, 1928, because of pains in the lower abdomen, "heart attacks," and "weakness and tiredness."

The pertinent features of her history are slight abdominal discomfort, (worse during menstruation) which commenced in 1917. During her first pregnancy (1921) prolapse of the uterus occurred, which increased after the birth of a normal child, the discomfort bordering on pain. A second childbirth (1923) accentuated both pain and prolapse. A repair operation (1924) afforded partial relief. For six months before admission to hospital indefinite lower abdominal pain, increasing backache, and a "dragging down" feeling in the pelvis, suggested to the patient a recurrence of the prolapse.

The history of tetany probably commenced in September, 1925, with a "heart attack," the first of a series, initially a week apart, but gradually increasing in frequency to one on alternate days. These ceased in February, 1926, but recommenced and ran a similar course from November, 1926, to February, 1927, and again from December, 1927 until admission to hospital. Glycosuria was reported in December, 1925, and the patient was kept on a rigid diet until October, 1927. There is no present evidence of diabetes.

The patient's description of these attacks accords well with subsequent accurate observations. She reported a sensation of "fluttering" of the heart, followed within a few minutes by a numbness of hands, feet, and head, which travelled towards the trunk. Then followed shortness of breath, "gasping," and a few minutes later the hands and feet became stiff. The attack lasted from a few minutes to one and a half hours. It passed off gradually, there remaining an aching pain in the muscles of legs and arms, a feeling of tiredness, and an increase in pelvic pain sometimes severe enough to keep her in bed for two or three days. During the attack she was forced to lie down, though never falling, and never losing consciousness. No involuntary movement of the bowels or bladder occurred. The "attacks" were started by such trivial causes as washing dishes, stooping climbing stairs, and have even occurred while she was in bed or resting in a chair. Usually no treatment gave relief, although during a severe attack which occurred just before she left for hospital some relief was obtained by administration of chloroform by her local doctor.

Her personal history revealed nothing pertinent.

Condition on admission.—Gynaecological condition (Dr D S Mackay), laceration of perineum with prolapse of uterus, dragging down of ovaries and pelvic congestion. No other positive findings.

Urine analysis on admission, cloudy, acid, sp gr 1.018, a very faint trace of albumen, sugar absent, a few pus and epithelial cells present. A very similar report two days later. A microscopical blood examination revealed nothing abnormal. The basal metabolic rate was +4 per cent.

Hospital History.—On the third day in hospital (January 23rd) the patient had a mild attack of tetany witnessed and accurately described by a nurse. It lasted between 10 and 15 minutes. Examination shortly afterwards showed a positive Chvostek's sign on the right side, and Trousseau's sign was positive with both arms within two minutes although Poole's phenomenon could not be elicited. Blood was taken six hours after this attack. The serum calcium was 9.5 mg per 100 cc.

On January 25th she slept well till 4 a.m., awakened with a frontal headache not severe enough to disturb her, had her usual breakfast at 8 a.m., and felt fairly well. At 9 a.m., while sitting in a chair waiting for her bed to be made, the usual preliminary symptoms of her attacks commenced, she was helped back to bed at 9.05, and numbness of the hands, wrists, and lower extremities half way to the knee began, followed rapidly

by stiffness of hands and legs. Drs Hunter and Monteith watched this attack from 9.15 a.m. till it ceased at 9.25.

She was conscious and quite emotional. Her breathing was very deep and gasping throughout, at first forty per minute, it increased within three minutes to sixty per minute. (The emotion and the breathing could be controlled by getting her to answer questions, which led Dr Hunter to the opinion that the attack could have been shortened, or at least controlled, by strong mental suggestion.) The heart rate was 80 to 90 throughout the attack.

The "accoucheur hand" was present, the feet were dorsiflexed, and the knees extended, with slight rigidity. At the height of the attack the head was drawn back and the face assumed a typical tetanoid appearance. The numbness disappeared with the attack itself, though the hands maintained a tendency to unnatural stiffness and position for the following half hour.

Chvostek's sign was markedly present throughout the attack (all branches of the facial nerve showed hyperexcitability), it could be elicited for the following twenty-four hours. Subsequently it was uncertain. Trousseau's phenomenon was markedly present throughout the day, and definite all the succeeding day. Poole's arm phenomenon was questionable, the leg phenomenon could not at any time be elicited.

Blood taken at the height of this attack had a serum-calcium value of 10.1 mg per 100 cc.

The patient stated that this was a mild attack. A few days later she had a very mild attack, not seen by a doctor. It passed off quickly. Trousseau's sign could be elicited afterwards, but the Chvostek sign was uncertain.

On February 4th, Dr D S Mackay operated, repairing the pelvic floor. The anaesthetic was taken extremely well and she made an uninterrupted and uneventful recovery. During this recovery period she experienced the preliminary phases of these attacks but they were easily controlled. Dr Hunter stopped one attack immediately by using mental suggestion. The nature of the attack was explained to her, and she was told that she could prevent it herself by controlling her breathing. She then found that whenever the preliminary "fluttering" of the heart became noticeable she could prevent any subsequent development by deliberate breathing control.

She was discharged from hospital on February 29th. At this time a 24-hour specimen of urine showed no trace of albumen.

In the last week of March there was some recurrence of abdominal pain, with the initial symptoms of tetany, coincident with onset of the menses. By control of her breathing she has been able to prevent these attacks reaching the stage of stiffening of the extremities, and although when she was last heard from (May) the attacks still recurred from time to time, she appears to be gaining increased control of them.

CASE 2

Mr K, Hebrew, aged 28, was admitted to the Winnipeg General Hospital on May 17, 1928, for examination.

History.—For several months he had experienced a feeling of fullness after meals, flatulence, and an inability to digest a fatty diet. On April 4th last, while driving his car, he felt a sharp needle-like pain in the epigastrium, which travelled upwards. He then had difficulty in breathing, deep rapid respiration set in, and this was followed within a few minutes by stiffening of the hands and feet, these extremities, from his description, behaving as in a typical tetanic spasm, while his face became contracted towards the right. The attack lasted between five and ten minutes, then the pain ceased, next the breathing became normal, and finally the spasm ended.

After ten days precisely similar attacks occurred,

and he was averaging about one a day when admitted to hospital. For two days before admission he had a steady dull pain in the epigastric region. During this period he saw Dr Burrige, who sent him to hospital for examination.

Hospital history—The essential features, from the standpoint of this paper, were as follows. Two or three typical attacks occurred during his stay in hospital. During the first, studied closely by one of us, he exhibited the "accoucheur hand," feet dorsiflexed, positive Trousseau and Chvostek signs, and presence of Poole's phenomenon (both arms and legs), while a sample of blood taken during the height of the attack gave a value for serum-calcium of 11.3 mg per 100 cc. The attacks were all preceded by pain, and immediately preceded by rapid deep breathing. They usually lasted ten minutes or less.

General examination was negative. A barium series gave negative results. A gall bladder test (Graham's method) gave faint visualization in sixteen hours. From the previous history of digestive disturbance and the gall bladder visualization test, together with the above study of an attack, Dr Burrige made a tentative diagnosis of cholecystitis, complicated by hyperventilation tetany.

It was explained to the patient that the tetany could be prevented by control of breathing. He was discharged from hospital on May 26th.

DISCUSSION

The first case is that of a tetany following lung hyperventilation arising from the continued discomfort of the pelvic condition, accentuated by various minor factors.

The second case is that of a tetany following lung hyperventilation set up by pain, probably due to cholecystitis, and thus resembling one of the cases reported by Goldman.

Education of the patient as to the cause of the attack, and the possibility of arresting it by control of breathing, seems indicated as a satisfactory form of treatment.

Although tetany following lung hyperventilation has been so rarely reported in the literature, yet, especially since several of the cases actually reported have been only single transient attacks, it seems just possible that a more careful watch for them may indicate that tetanic attacks of this type (especially slight ones) may be in reality not so uncommon.

A FATAL CASE OF MUMPS

By G. G. LECKIE, M.D.

Lucky Lake, Sask.

The following case is reported chiefly as a warning to any who may be inclined to treat parotitis of the epidemic variety as a disease void of any danger.

An epidemic of parotitis prevailed at the time, practically all susceptible children in the neighbourhood were attacked, yet they did not complain except for one or two days at the commencement of the infection, and would not remain in bed longer.

CASE REPORT

A farmer, aged 42, in the best of health previously, he had never been ill except with children's diseases.

He was first seen on January 10th, when he had a slight unilateral swelling, with fever, and malaise. A diagnosis of mumps was made.

On the 21st he was seen again, and then complained of weakness of the arms and legs. He said he had remained indoors since I had seen him, except the day before, when he had gone only as far as his barn, but had to return because he felt weak. On returning to the house he could not raise his arm to hang his coat or hat on a peg, and was helped to the bedside.

On examination, the swelling which he said had been very marked, extending down his neck and even over the clavicle on the one side, had not entirely subsided. The temperature was normal, pulse rate, normal, knee-jerks, sluggish, the plantar reflex, not elicited, the abdominal reflex, present, arm reflexes could not be elicited.

The following day he was no better.

On the 23rd I again examined him. Now he could not raise his legs or arms at all, yet he could move his fingers and hands freely. He lay quite helpless. Knee-jerks, absent, Babinski reflex, present, abdominal reflex, absent, temperature and pulse, normal.

On the 24th, he was as above, but complained of dryness of the tongue and throat, slight difficulty in articulation, and had dysphagia and dyspnoea.

The same day, eight hours later, he could speak only in a whisper. His breathing was thoracic entirely, with increasing cyanosis. Finally, artificial respiration revived him for

two hours, when he died of asphyxiation, conscious until artificial respiration ceased

The diagnosis of acute ascending paralysis, complicating mumps, was made.

LYMPHOID LEUKÆMIA AND TUBERCULOSIS*

By J. FEIGENBAUM, M.D.,

Montreal

A rather unusual case of lymphoid leukæmia with several interesting features was recently observed on the Medical Service of the University of Michigan Hospital. The following is an excerpt of the history, physical examination, laboratory and necropsy findings

G. E. J., (No 185483), male, aged 56, labourer, was admitted to the hospital on December 24th, 1927, complaining of "lumps in the neck," a failing appetite, loss of weight, weakness, and pains in the abdomen. The patient dated the onset of this illness one year ago, December, 1926, when he noted two lumps in the upper part of the neck. Three months later, similar masses appeared in the various lymphadenoid situations of the neck. These masses were at first painless and hard, but subsequently, certain of them softened and ultimately broke down, discharging a thick creamy material. A thin discharge then continued for one to two weeks, when the opening in the skin closed. This was not invariably the course of events, however, and a sinus with its mouth over the episternal notch had oozed intermittently for six months. Weakness was so marked for six months that it entirely incapacitated the patient. Emaciation was progressive and a loss of fifty pounds in weight had occurred. On July 1, 1927, the patient was seized with severe, colicky pain in the abdomen, which subsided after a few days, but returned about the middle of December 1927, to recur persistently after taking solid food or fluids. Associated with this pain there was diarrhœa. During an interval of four weeks, in the summer of 1927, deep jaundice was present. For one month before admission the patient suffered from a moderately productive cough, with hoarseness. Weakness had been marked for six months, and anorexia had been present ever since the beginning of the patient's illness. Dysuria occurred on several occasions during the period of ill health.

Physical Examination.—On admission the patient showed a temperature of 99.4 degrees F., a pulse rate of 104 per minute, and respirations 28 per minute. A hypotension of 90/50 was present. Emaciation was pronounced, and the patient appeared acutely ill when he was first observed. There was a well marked arcus senilis. The lips were pale, the tongue, buccal mucous membrane, and the palate were abnormally dry. The tonsils were moderately enlarged. The neck presented the most puzzling findings of the whole physical examination. An elongated swelling was visible along the anterior border of the left sterno mastoid, and a round mass about the size of a walnut above the sternal end of the right clavicle. Fluctuation was obtained over both of these. Two scars, evidence of old sinuses, were present on the left side of the neck while at the right base of the neck there was an open, ulcerating, indurated and painful surface, about the size of a quarter. The posterior cervical lymph nodes on both sides of the neck

were as large as marbles. They were tender, matted together, and adherent to the subcutaneous tissues, though the skin over the nodes was perfectly free. The right axillary as well as the epitrochlear and inguinal lymph nodes on both sides were slightly enlarged. Over the right supraspinous fossa an impaired percussion note was obtained, with accentuated breath sounds over this area and over the first right interspace and interscapular regions. The heart sounds were distant. The abdomen was distended, and diffuse tenderness made palpation unsatisfactory. Rectal examination was extremely painful, but revealed no further abnormalities. Cyanosis of the nail beds was well marked.

Laboratory Examinations.—The urine showed a very faint trace of albumen. A negative blood Wassermann reaction was obtained. The blood picture revealed red blood cells, 4,060,000 per cmm., white blood cells, 89,400 per cmm., and hæmoglobin 42 per cent (Sahli). White blood cell counts of 64,500, 105,500, and 85,800 per cmm. were obtained on three subsequent occasions. The differential blood count was interesting, polymorphonuclear neutrophils 2 per cent, small lymphocytes 4 per cent, large lymphocytes 3 per cent, and monocytes 91 per cent. The red blood cells were pale, round, and they showed marked anisocytosis (Fig. 1). A few normoblasts were found. Some phagocytic monocytes were noted in the blood film, and several hæmohistioblasts of the monocyte or lymphocyte series. An examination of the stool showed a faint trace of occult blood. Aspiration and culture of the fluid from the cystic swelling over the sternal end of the right clavicle yielded a growth of *S. aureus*. This was probably the result of a contamination, because a later culture from the same source remained sterile. The blood non-protein nitrogen content was 58.4 mgm per cent. A roentgenogram of the chest revealed several Ghon's tubercles in the left lower lung field.

Course in the Hospital.—The patient's condition on admission was very poor, and became progressively worse during the few remaining days of his life. He was very uncooperative, and during the last three or four days delirium supervened. There was a troublesome diarrhœa for one week preceding death. The temperature during observation ranged between 97 and 100 degrees. On January 2, 1928, signs of consolidation became evident over the right lower lobe of the lungs. The patient then lapsed into coma, and died a few hours after this.

Autopsy.—(2539 A 122 AF). The external examination as recorded in the autopsy protocol did not disclose anything not already given under physical examination.

The spinal cord, brain and meninges showed no abnormalities. Old calcareous foci were present in the left upper lobe of the lungs, with adhesions about the apex of the right lung and caseous tubercles in the lymph nodes at the hilum. There was a marked hypostatic congestion of the right lower lobe of the lungs, probably terminal. A complete synechia cordis was found, while the heart itself showed no striking changes. The thickened omentum presented many nodules varying in size from a pin point to a pea, and was adherent to coils of small intestine. The edge of the liver extended 16 cm. below the ensiform cartilage, the spleen was slightly enlarged. Tubercles studded the peritoneum, the spleen, and the intestines. The mucous membrane of the transverse colon showed ulcerations in its circular axis. Two small ulcers, one-half centimetre in diameter, were present in the duodenum, one, just beyond the pyloric ring and the other, four cm. below the pylorus. On the lesser curvature of the stomach there were two ulcers, penetrating through the wall of the stomach, and leading into a large mass of pancreatic tissue behind. The peri-pancreatic lymph nodes were enlarged, and several were soft and necrotic. The mesenteric lymph nodes were also enlarged and contained tubercles and small abscesses. An occasional tubercle was seen on the surface of the liver. The bone marrow was soft and light red in colour.

* From the Department of Internal Medicine, University of Michigan Medical School, Ann Arbor

Microscopically, leukæmic clots were visible in all the blood vessels. The spleen showed leukæmic metaplasia, with numerous large caseating tubercles. The mucosa, submucosa and subserosa of the entire alimentary tract had become involved in the leukæmic process. Sections showed this to be the case also in the omentum, pancreas, liver, gall bladder, adrenals, kidneys and urinary bladder. A marked chronic interstitial inflammation was observed in the pancreas, with non-tuberculous sinus tracts traversing that organ. Tubercles were demonstrated in the liver, kidneys, and retroperitoneal lymph glands, while the mouth of the sinus in the neck showed tubercles in pyogenic granulation tissue. The bone marrow had undergone lymphoblastomatous metaplasia.

COMMENT

As has been seen, this case presents many unusual findings both from the clinical and the pathological side. The striking fact is, of course, the association of a leukæmia with widespread tuberculosis. The co-existence of the two diseases has been recognized for a long time, and has been noted by various authors. Thus Osler¹ in his text-book says that tuberculosis is not an uncommon complication of leukæmia, and cites Dock,² who collected twenty-seven cases from the literature. Many of our observers, however, stress the frequent occurrence of tuberculosis in myeloid leukæmia, but fail to mention its incidence in lymphoid leukæmia. Karl Vogel,³ in his discussion of the complications which are met with in the leukæmias, intimates that tuberculosis is frequently present in the myeloid variety, but passes over its occurrence in the lymphoid type. Nanta⁴ has gathered thirty-seven cases from the literature and added observations from one of his own cases, in whom both myeloid leukæmia and tuberculosis were present. Only passing reference is made in this review to the association of lymphoid leukæmia and tuberculosis. Ordway and Gorham,⁵ while pointing out the etiological relationship which is supposed by some to exist between these two diseases, dismiss the subject by stating that "the actual co-existence of tuberculosis and leukæmia is rare." Richard Cabot⁶ maintains that tuberculosis is not uncommon as a complicating factor in lymphatic leukæmia. R. R. Dietzele,⁷ in 1916, reported a case from the pathological department of this clinic which bears a remarkable similarity to the one recorded above. The autopsy brief of Dietzele's case states in part "chronic lymphatic (mixed lymphoid myelogenous) leukæmia, primary tuberculosis of the cervical glands, acute miliary tuberculosis of all organs, includ-

ing the skin, multiple lymphomata of kidneys and liver, leukæmic infiltrations of the gall bladder and intestine." P. Emile-Weil and Coste⁸ cite a case in a male of 26, whose chief complaints were fever, cervical adenopathy, and a tendency to hæmorrhage. This man's white blood cell count was 54,000 on admission, but rose later to 90,000. At the onset, the whole picture was that of a myeloid leukæmia, but later it assumed the form of a lymphoid leukæmia. From their description, however, the myeloid leukæmia probably developed into the myeloblastic type, which is often confused with lymphatic leukæmia. Lymphomatous infiltration of the hæmatopoietic organs with miliary tuberculosis was disclosed at the post-mortem examination.

The blood smear in the present instance offered material for an interesting study. As will be remembered, the majority of the white blood cells were of the mononuclear variety (91 per cent). Many of these were large cells having circular deeply staining nuclei and a lighter staining cytoplasm, with numerous small basophilic granules sprinkled throughout. Such cells have been classified in the lymphatic series and have been seen in cases of acute lymphoid leukæmia.⁹ This lends some support to the impression that the patient, when seen here, was suffering from an acute exacerbation of a chronic lymphoid leukæmia. The majority of the mononuclear cells were of a different variety and consisted almost entirely of large nuclei, usually notched, with chromatin more deeply staining than that seen in mature lymphocytes. A tiny segment of cytoplasm opposed to the nuclear indentation completed the morphology of these cells. Lymphoblasts are larger cells and have a more abundant cytoplasm. It is obvious that the blood picture *per se* was not entirely characteristic of lymphoid leukæmia. Landon¹⁰ believes that a diagnosis of lymphoid leukæmia should be made only with caution in the presence of a mononucleosis even with a marked leukocytosis. He reports two cases in confirmation of this view, in one the diagnosis proved to be infectious mononucleosis, and in the other an acute form of pulmonary tuberculosis.

Another feature of interest is the presence of a virulent form of tuberculosis in the presence of an excess of lymphocytes—the type of cell

which is usually associated with immunity in tuberculosis. It is suggestive that the so-called lymphocyte of lymphatic leukæmia is not identical with the normal lymphocyte of the circulatory blood, but bears the same relation to it as does the cancer of the breast cell to a normal cell in the breast tissue.

FIG 1—Oil immersion field of blood film showing atypical monocytes. The red blood cells show definite anisocytosis. (Camera lucida drawing)

The diagnosis in this case was obscured considerably by the necrosis which had occurred in the lymph nodes of the neck. So far as could be ascertained, there is no reference in the literature to breaking down nodes in lymphatic leukæmia. Indeed, the sinus tract in the neck, together with the sterile culture obtained from the necrotic mass, suggested rather strongly a tuberculous process in the lymph nodes.

The multiple non-tuberculous ulcerations met with in the stomach, duodenum, and colon presented another problem for explanation. It is probable that these ulcers did not exist prior to the patient's final illness, as there was no history of gastro-intestinal disturbance before his illness. While gastric and duodenal ulcers may be symptomless, ulcers of the colon seldom are. It is very likely, then, that the defects in the mucous membrane observed at autopsy followed the leukæmia. As has been seen the widespread lymphoid infiltration did not spare the mucous membrane of the gastro-intestinal tract, and it is quite possible that the chemical

and mechanical irritation of the digestive juices and food succeeded in producing death in tissues which had become *loci minoris resistentiæ* (infiltrated with lymphoid cells).

The reason for tuberculosis following upon a leukæmia seems obvious. The ability of the body to cope with infection is reduced by a chronic illness, leukæmia. Tubercle bacilli which have been encapsulated and dormant for years become active, and a dissemination of the bacilli produces miliary tuberculosis. It is interesting to note that at one time this case might have been cited as proof for the tuberculous etiology of the leukæmias, in spite of the distinct microscopic pictures produced by each disease.

SUMMARY

- 1 A case is reported of lymphoid leukæmia co-existing with tuberculosis.
- 2 Attention is drawn to the few references of this combination of diseases in the literature.
- 3 The atypical blood picture in this case, together with certain clinical features, suggested two diseases rather than one.
- 4 The lymph node of lymphatic leukæmia apparently never breaks down, unless secondary infection has taken place in it.
- 5 The occurrence of tuberculosis in lymphatic leukæmia can best be explained by regarding the tuberculous process as an expression of lowered resistance in the patient.

My thanks are due to the pathological department for permission to make use of the autopsy record and to Drs C C Sturgis, H Field, and R Isaacs for their kindly advice.

Editorial

THE ANNUAL MEETING AT CHARLOTTETOWN

THE Canadian Medical Association held its annual meeting this year at Charlottetown, P E I. This was the 59th annual convention since its foundation in 1867, but it was the first time the Association had come to "The Island". If, however, the success of this meeting is to be a sufficient precedent, this site has gained a permanent place in the list of those to be considered in other years.

What makes for the success of such gatherings? The place of meeting may have peculiar attractions of its own, there may be large numbers in attendance, the occasion may be marked by the announcement of great developments in medicine. But one cannot expect all these conditions, nor would it be anything but an unnecessary and invidious task to try to apportion them to each occasion. What, above all, must preside at a meeting of this sort is the spirit of hospitality, and how strongly it was in evidence at the Charlottetown meeting will not readily be forgotten, especially by those seeing Prince Edward Island for the first time. The natural beauty of the island, the excellence of the program, the evident enthusiasm of those in attendance, all contributed to a sense of success, but one's memory will longest retain the warmth of welcome and the continual entertainment which was so whole-heartedly offered by what seemed to be the entire population.

Those who planned this meeting could not have had a happier inspiration than that of chartering a steamer for those from Quebec and western points. The S S "New Northland" carried but a small proportion, it is true, of those attending the convention, but they were representatives of every province from Quebec to the Pacific Coast, and before the cementing influence of the convention itself began, the association on board had gone far in the establishment of cordial friendships and understandings. In Charlottetown, too, the boat became a centre of interest and entertainment, enabling

the ladies of the party to return in some degree the hospitality shown them in such good measure by the hosts and hostesses of the Island. In future, no convention should be considered complete without some such introductory boat trip!

Two full days were taken up with meetings of the Council, and the volume of business transacted might easily have encroached on even more time if the chairman had been one of less experience and firmness. In this Parliament of the Association there is much to be learned, and not least the principle of consideration for the opinions of all its diverse members. There can be few other medical Associations whose various parts possess such varying characteristics and problems as the provincial daughter societies of the Canadian Medical Association. There certainly can be no other Association in which these minor differences are more successfully harmonized. How wise a suggestion it was that henceforth one or more of the most recent graduates should each year be appointed to sit on the Council to follow its deliberations. The work of the Association itself is naturally of a specialized order, and demands men trained in administration, but no better demonstration of its functions could be given, and in no quarter where it would be more effective, than by some such plan as that mentioned.

One must be impressed by the variety of objects in which the Association is interested, and by the progress attending all that it takes up. What does the future hold for it? Judging by the confidence and zeal of its members, only the best things, those most nearly approaching its ideals. But that cannot be all. Full of vigour and promise as the Association is, it still will meet its difficulties and troubles. This thought was well expressed by one member,* who saw in this particular meeting something of a pause for the gathering of new strength.

* Dr G H Murphy

It was as if the Association, with all its achievements behind it, and its hopes and plans before it, had withdrawn to one of the most quietly beautiful parts of Canada, not attempting to bring together great numbers, nor to celebrate any special scientific

advance, but chiefly to regain that impetus which its work will demand of it in steadily increasing measure. Is there any other place in Canada from whose historical associations there could be derived a keener stimulus to unity and high purpose?

PUERPERAL SEPSIS

WE are publishing in this issue an abstract of an address by Dr James Young, of the Edinburgh Royal Maternity Hospital, delivered before the Edinburgh Obstetrical Society, on Maternal Mortality from Puerperal Sepsis, a subject which is engaging much thought in the profession both in Great Britain and in America, and deservedly so. In Canada attention has been called to the unnecessarily high mortality connected with maternity practice, especially in the outlying districts of our several provinces, and the statistics elicited by the recent questionnaire of Dr Helen MacMurchy present an urgent problem to our profession.

In Great Britain, the Council of the British Medical Association, recognizing the need for investigation, appointed in 1924 a special committee to enquire into the causation of the high puerperal morbidity and mortality. In its report this Committee calls attention to many possible factors of which our knowledge is defective and on which experimental research is necessary. Undoubtedly, all hospital records point out the increased evidence of morbidity which arises from unnecessary intervention, and to the fact that the morbidity risk increases the higher up in the genital tract the manipulation extends. In an editorial on this subject, the *British Medical Journal* makes the suggestion that while an increase may have taken place in the number of skeletal defects in mothers, resulting from the survival of many rachitic children who, owing to imperfect care, would have succumbed in the past, nevertheless, the important change which has taken place in the child-bearing women of to-day is the peremptory call for the relief of pain and the shortening of the period of travail by means of anaesthetic drugs and the forceps. Medical

attendants are chosen largely from those who will afford this relief, and accoucheurs have to steer the difficult course between the strongly expressed desires of their patients, associated with the urgent demands of other branches of work, and what they may recognize as the safe course to take.

Dr Young in his address insists on the need of educating the public to the realization that at the present a price must be paid for the relief which the parturient mother in so many instances imperiously demands, and pleads for the importance of securing, so far as may be, practicable natural delivery. The statistics he presents are worthy of careful thought by the profession, and the suggestion of team work between doctor and trained midwife would appear in many respects to be a valuable one.

The preliminary report by Dr Burt White of his investigations on the varying resistance of puerperal women to streptococcal vaccine appears to indicate that those who react to this toxin are more liable to puerperal fever than those who do not,—an interesting fact which may prove valuable. His experiments may be briefly summarized as follows. In an investigation of 100 pregnant women 27 proved sensitive to a dose of scarlatinal toxin, 1.5 c cm of a dilution of 1 in 1,000 strength. Eight, or 30 per cent, of these sensitive women experienced a morbid puerperium, though labour was altogether normal. Seventy-three gave no reaction, of these, two had a morbid puerperium, but in neither of them could streptococci be found in the cervix or in the blood. Thirteen of these non-reacting women sustained difficult labour but had a satisfactory puerperium, and in no instance did the bacteriological examination reveal the presence of *streptococcus pyogenes*.

His inference was that women who react positively to intradermal inoculation of scarlatinal toxin are more liable to develop puerperal sepsis than those who do not react. The comment in the editorial in the *British Medical Journal* is to the effect that,

once knowledge of this kind has been definitely established, and it becomes possible not only to pick out those in whom the power of resistance is low but in the pre-natal period to raise the resistance, the risks of artificial aid may be greatly lessened

ALEXANDER GORDON OF ABERDEEN

IN connection with the above we note the very charming reference to the brochure by Alexander Gordon of Aberdeen, entitled "A Treatise on Epidemic Puerperal Fever in Aberdeen," published in 1795, which appears in the *American Journal of Obstetrics and Gynecology*, February, 1928, from the pen of Herbert Thoms, of New Haven, Connecticut.

Alexander Gordon was born in 1752, took his degree of M.A. at Marischal College, Aberdeen, and began the study of medicine first at Aberdeen Infirmary, but later on in Edinburgh. He joined the navy as surgeon's mate in 1780, and two years later obtained the rank of surgeon. In 1785 he retired on half pay and came to London, where he became a resident pupil at a lying-in hospital, and attended lectures on midwifery by Denman and by Osborn. He afterwards attended lectures at Westminster Hospital. After this training he returned to Aberdeen and obtained his degree of M.D. Shortly after, he was appointed physician to the dispensary, and obtained an excellent reputation and a large practice in which he devoted himself chiefly to obstetrics. Four years before his death he was again summoned by the Admiralty for active service in the Navy, but speedily developed tuberculosis and was invalided home. His death took place in 1779 when he was forty-seven years of age. The *British Medical Journal*, June 9, refers to Dr. Thoms' article as follows—

"Dr. Thoms cordially agrees with A. W. W. Lea, who maintained that Gordon was to be credited with having first clearly demonstrated the infectious nature of puer-

peral fever. Oliver Wendell Holmes was so much impressed with Gordon's treatise that in his essay he quoted the following paragraph in capital letters: "By observation I plainly perceived the channel by which it was propagated, and I arrived at that certainty in the matter that I could venture to foretell what women would be affected with the disease, upon learning by what midwife they were to be delivered or by what nurse they were to be attended during their lying-in, and almost in every instance my prediction was verified." With extraordinary honesty Gordon continues: "It is a disagreeable declaration for me to mention that I myself was the means of carrying the infection to a great number of women." In another important passage he shows the analogy between puerperal fever and erysipelas, in both of which the infectious matter is readily absorbed by the lymphatics in the vicinity of the wound. Gordon not only demonstrated the infectiousness of puerperal fever, but had a definite idea of the pathology of the condition, whereas his contemporaries Hulme and Lake pronounced the omentum to be the seat of the disease. Gordon by his dissections showed that puerperal fever was a disease which principally affected the peritoneum and the ovaries. Lastly, he laid down the following rules for prophylaxis: "The patient's apparel and bedclothes ought either to be burnt or thoroughly purified, and the nurse and physicians who had attended patients affected with puerperal fever ought carefully to wash themselves and get their apparel properly fumigated before it is put on again."

BRUCELLA FEVER

THE publication in this issue of the *Journal* of a paper by Drs Scozzafave and Warner, of Welland, Ontario, on the subject of *Brucella abortus* infection in man, should serve to focus the attention of the Canadian medical profession on a new, and what promises to be a serious, public health problem.

The microorganism, known as *Brucella abortus* is the cause of contagious abortion in cattle, and is closely related to, if not identical with, *Brucella melitensis*, the specific cause of Malta fever. It is generally known that Malta fever, found originally in goats, is communicable to man, and it has been suspected for some time that *Brucella abortus* might, on occasion, be pathogenic for man also. Convincing evidence in favour of the latter possibility, however, was not obtained until 1924 when Keefer described a case, which he called Malta fever, but in which an organism conforming exactly to the type of *Brucella abortus* was isolated (*Bull Johns Hopk Hosp*, 1924, xxxv, 6).

The specific cause of Malta fever, also called Mediterranean fever and undulant fever, was discovered by Sir David Bruce in 1887. The disease is constantly to be found in countries bordering on the Mediterranean Sea and in the districts adjoining. It was apparently introduced into the United States about twenty-five years ago. The first case was recorded by Craig (*International Clinics*, Phila., 1905, xxi, 576).

Evidence is accumulating to indicate that Malta fever is gradually gaining a secure foothold in the country. The extent of the menace, however, can hardly be estimated at the present time, or until medical men generally become alert to its presence.

The work of Evans (*J Infec Dis*, 1918, xii, 576) shows that *Brucella melitensis* and *Brucella abortus* cannot be distinguished culturally or morphologically. Even the most refined serological tests can hardly make a distinction. These conclusions have been confirmed by several later workers.

Infections with organisms of the genus

Brucella occur in goats, cattle, horses, pigs, and human beings. Little is yet known as to the extent of these infections and the modes of transmission.

In so far as man is concerned, the clinical features of Malta fever and infection with *Brucella abortus* are so similar as to be indistinguishable. This is to be expected in view of the close relationship and probable identity of the two micro-organisms. In view of these facts the suggestion of Drs Scozzafave and Warner that the term *Brucella abortus* infection should be applied in the future to this disease is worth considering. But why not the simpler "Brucella fever"?

It is a matter of prime importance that the general practitioner, especially, when he meets with an obscure case of continued fever, that is not typhoid or paratyphoid, should think of Malta fever or infection with *Brucella abortus*. At present the diagnosis must be made by laboratory methods. It is not enough that a Widal test be done in cases of this character, but further tests should be carried out with the indicted strains of *Brucella*. This procedure, carried out as a routine, would likely do much to clear up a somewhat hazy situation. Something more would be learned in regard to the relationship existing between *Brucella melitensis* and *Brucella abortus*, their relative distribution, and the extent of their invasion. Much more, too, might be learned about the clinical symptomatology and the sources of infection. Up to the present time only severe cases have been studied, probably many mild cases have gone undiagnosed.

Should it be found that Malta fever and *Brucella abortus* infection are prevalent in Canada, it should be a relatively easy matter, by a study of these diseases in goats and cattle, and possibly in other of the domestic animals, to locate the source of the trouble and the manner of its spread, and to deal with the problem intelligently and effectively.

promote progress. In any case, one of the constituents of bios is almost certainly necessary for the animal organism. According to Keil, bios can be resolved into three fractions, each necessary to the growth of yeast. One is a crystalline compound having the formula $C_5H_{11}NO_3$, the second, apparently a basic substance, is probably a derivative of indol and so related to the amino-acid tryptophane, and the third is Lash Miller's bios.

Professor Lash Miller, of the University of Toronto, and his co-workers, after prolonged study, have just made the important discovery that this fraction, which he had previously termed Bios I, is *inositol*. Inositol $C_6H_6(OH)_6$ is a derivative of benzene, in which to each of the carbon atoms of the benzene ring is joined an atom of hydrogen and a hydroxyl radical. It appears to be necessary not only to the plant, but also to animals. Its importance is only slowly becoming recognized. In plants it occurs free, and also united with phosphoric acid, calcium and magnesium, as the compound

phytin. Plants contain a special ferment phytase, which splits phytin into its components.

Inositol is present in traces in our muscles and other tissues, and in urine. While for long it was thought that this was merely accidental, due to the ingestion of plants containing it, recently Needham has shown that it is actually formed from glucose by the developing egg-embryo, from which fact there is a reasonable assumption that it has a definite function in the animal.

It is probable that the complete list of vitamins is not yet known, but we are coming to full realization of the importance of these compounds, minute amounts of which, in collaboration with similarly minute amounts of the endocrine secretions and the ferments of the body, control so delicately its vast and complex chemical mechanism. Yet we have still to learn the most important facts about them. What are the functions of these vitamins in the normal living organism? How do they act?

A SECTION OF HISTORICAL MEDICINE IN THE CANADIAN MEDICAL ASSOCIATION

The arrangement of subjects in "Sections" is a convenient plan for dealing with specialized knowledge, and may sometimes even be looked upon as marking a kind of coming of age of the specialty so set apart. It is not so long ago that anæsthetics and radiology gave this evidence of their growth, and now there has been added to the list of Sections that of Historical Medicine*. This differs slightly, however, from the others in the intentions behind its formation, for where the interest in a section such as radiology, let us say, will necessarily be largely confined to those working with x-rays, that of historical medicine, it is hoped, will be a common meeting ground for all medical men. The historical aspect of medicine is one which may be more constantly in the minds of some than of others, and naturally there will be those whose knowledge of it will be wider and fuller, but there can be very few for whom it does not at some time, or in some respect, hold the fascination that lies in contemplating all that has gone and is going to the growth of our profession. There is no technical qualification

necessary for the appreciation of history or for contribution to its records.

The work which the Section will undertake, will, in general, be the presentation to the profession of matters of historical interest in medicine. There are signs of increasing efforts to gather together the records of early medical conditions in Canada, and much has been done to permanently preserve the reminiscences and experience of those whom we are fortunate in still having with us. But still more can be done in the preservation of records, and it will be not the least of the Section's work to foster all attempts to do this. There is at present no convenient place in which a central historical museum could be formed, and it is doubtful if one ever will come into being, but there is all the more need for separate collections or museums, and for the collation and record of their contents. This historical material scattered as it may be, should, however, always be available for those who wish to make use of it under the aegis of the Section. At the annual meeting in Montreal next year for example, there should be little difficulty in displaying a great many unique records and medical historical relics. In the following year fresh stores should be available in the locality chosen.

No attempt will be made to limit the interests

* Organized at a meeting held in Charlottetown, P. E. I., during the week of the Annual Convention, June, 1928.

f the Section to Canada alone. It was thought, however, that attention should be concentrated here at first, especially as there is so much in Canada that should be collected. The *Journal* has been fortunate, in recent years, in receiving many important and well written historical contributions. It is hoped that these will continue to be sent in. The *Journal* should, indeed, as with all other matters pertaining to Canadian medicine, be the natural channel through which much of the work of the Section of Historical Medicine will reach the profession at large.

THE CANADIAN MEDICAL PROTECTIVE ASSOCIATION

The Canadian Medical Protective Association held its twenty-seventh annual meeting at Charlottetown during the course of the meeting of the Canadian Medical Association. Some important business was dealt with, and it will be of interest to bring the proceedings to the attention of the profession in Canada generally.

As will be remembered by the members of the Protective Association, a questionnaire was sent out last year, asking for opinions on the advisability of increasing the annual fee to \$5 00, of which sum, \$2 00 was to be set aside as a fund to deal with certain cases that might arise, in which damages were assessed against a member whose case had been fought out and lost. There had been a feeling for some time that such a fund should be built up, but the executive did not feel that they could encroach upon the present resources of the Association for it, unless the whole membership showed themselves willing to accept possible future assessments that events might make necessary.

The replies to this questionnaire were overwhelmingly in favour of the proposed increase in the fee, and in view of this the President brought forward the by-law necessitated by the alteration. This by-law authorizes the setting aside of 40 per cent of the annual \$5 00 fee as an indemnity fund to meet the possible exigencies mentioned, and also permits of a further assessment of \$5 00 in case of the indemnity fund becoming exhausted. It is felt by the executive, however, that the fund so formed will be quite sufficient to meet any likely contingencies and that the probability of any further assessment is extremely remote.

The experience of the Association's officers enabled them to feel fairly secure in this expectation, since they had been engaged for twenty-seven years in protecting the interests of medical men in the law courts. In that time the Association had lost only one case, and the damages had not amounted to more than \$1,650 00.

It is to be remembered that many of the cases handled by the Association never go to court at all. Even if proceedings are threatened, it usually turns out, in at least three out of four cases, that acceptance of the writ by the Association's general counsel, Mr. Chrysler, K.C., is sufficient

to arrest proceedings. Still, in those cases that do go before the courts, the legal proceedings are usually expensive, whether the Association wins or not. In one case the costs amounted to \$4,000 00, by the time it was successfully fought through to the Court of Appeal.

Of course such expenditures are expected, and are quite cheerfully made, but the membership of the Association needs considerable strengthening before it can face many such calls on its treasury with complete equanimity. It is, therefore, with a feeling of satisfaction that we chronicle the acceptance of the by-law mentioned, under the operation of which the finances of the Association will be materially strengthened. It only requires ratification by the Governor-in-Council, after which it will come into force on January 1, 1929.

The following are extracts from the proposed amendments to the by-laws—

"12 The annual membership fee shall be five dollars, payable on or before the first day of January, in each and every year. Any person joining after July first shall pay half rates for the balance of that year.

"14 Each member will be required to guarantee the payment of a further five dollars if called upon, but such call will only be made in the event of the indemnity fund becoming exhausted.

"18 Delete

"19 When the Association decides to assist in the defence of an action against one of its members, it will undertake to pay the taxable party and party costs reasonably and properly incurred along with reasonable and proper witness fees and counsel fees to be settled by the General Council of the Association, and such costs shall be paid out of the funds of the Association.

"(a) If in any such case a verdict shall be obtained against such member, the Association agrees, if necessary, to pay the amount of such verdict up to an amount not exceeding five thousand dollars, and such costs as are properly taxed against him, provided that the Association will only pay, or contribute to the payment of damages, when the Council of the Association, upon consideration of all the facts of the case shall be of the opinion that the said verdict is one that should not have been given.

"(b) The Association will not pay in respect of damages assessed against any one member, any greater amount than five thousand dollars, once, in any one year."

THE MENACE OF THE MOTOR

The number of accidents, fatal or otherwise, due to motoring, is nothing short of appalling. One only has to look at the daily newspaper to realize this. There are many reasons for it. Some of them are so obvious that we need not dwell upon them. It is said that in the United States there is one motor car for every five persons, in Canada there is one for every eleven, and the number is steadily increasing. In the Province of Quebec alone, five thousand more cars have been registered this year than in 1927. This enormous increase of traffic, in streets not designed for the purpose, in itself constitutes a potential danger. Add to this, the great proportion of cars "of ancient vintage" in all stages of decrepitude, some of them indeed, all but defunct, the mechanism of which is apt to fail at the critical moment, and it can be seen that the danger is magnified. And besides this there is the personal factor.

But the hazard to the pedestrian and the motorist himself, through collision, is not the only one. The introduction of the so-called "ethyl gasoline" suggests another. This new type of fuel contains about one part in a thousand of lead tetra-ethyl. Some fatal cases of lead poisoning have occurred in the United States among men handling the lead compound, and lead has been found in the excreta of those working in garages where ethyl gasoline is sold. The special importance attending this particular lead compound lies in the fact that it is very readily absorbed and its effects are cumulative. It is soluble in oil and can penetrate an intact skin. This being so, and with the increasing popularity of the preparation as a motor fuel, health authorities have become very much alive to the new situation. The special dangers lie in the inhalation of the fumes, with the possibility of carbon monoxide poisoning superadded, and in the spraying of the streets with a compound of lead in a fine state of division. In the United States careful enquiry has failed to show that any actual harm has resulted in any case from the use of ethyl gasoline. But this conclusion is only provisional. Drivers of cars using ethyl gasoline showed no definite signs of lead absorption after exposures approximating two years. The Committee of the United States Federal Government came to the conclusion that there was no definite ground at the present for prohibiting the use of lead tetra-ethyl in motor fuel, provided its use and distribution were properly regulated.

In Great Britain this matter has elicited considerable interest also, and has led to interrogations in parliament, and the appointment of a special committee of enquiry under the Ministry of Health. This committee has come to the same conclusion as the American authorities. They advise, however, that ethyl gasoline be not used for cooking or cleaning. It seems evident that much more time must elapse before the effects of possible accumulation will become evident, and the danger be accurately appraised. In the mean time an attitude of watchful waiting is indicated.

Another menace, which is probably more serious, is poisoning with carbon monoxide, which forms about five to six per cent of the exhaust gas coming from automobiles. All are, or should be, familiar with the danger attendant on running the engine of a motor car in a closed

garage. It is stated that an average-sized engine, running under these conditions for one minute and a half will pollute the air to a dangerous degree. Occasionally, we hear of deaths from this cause. It is not generally appreciated, however, that, short of causing death, carbon monoxide is capable of producing unpleasant, not to say disastrous, results. In this issue of the *Journal* is a very carefully prepared and thorough article by Dr J. C. S. Battley, which will well repay perusal. The writer quotes W. J. McGurn, who studied carefully fourteen patients suffering from chronic carbon monoxide poisoning, in whom hereditary and otherwise acquired disease could be excluded. They exhibited various manifestations of toxic nerve irritation, such as peripheral neuritis, combined cerebrospinal and peripheral nerve lesions, multiple sclerosis, petit mal, convulsions, stupor, insanity, and, sometimes, glycosuria, permanent muscular weakness, vasomotor disturbances, and hyperpnea. It appears from this article, also, that a very small amount of the gas, when absorbed, can produce very serious symptoms. The physical characters of the gas are such that it can be inhaled in small amounts unwittingly for long periods, and its etiological relation to the nervous manifestations may therefore be quite unsuspected. While there is no need for panic at the present time in regard to chronic carbon monoxide poisoning, it is again a case for watchful waiting. We note that the Board of Health, in New York, is approaching the automobile manufacturers to see if it be feasible to have the exhaust gases discharged overhead, and not along the ground, in the hope that this will lessen the risk which undoubtedly exists in congested traffic.

THE SENIOR EDITOR

At the time of the Annual Meeting in Charlottetown the Council cabled a congratulatory and grateful message to our senior Editor, Dr Blackader, who is in England. It was the occasion of his birthday.

A reply received by letter indicates that the message was much appreciated, and that he looks forward hopefully to a continued improvement in the character and usefulness of the *Journal*, with the assistance of the augmented editorial staff.

That you may understand what it is that heals wounds, for without that knowledge you may not readily recognize the remedy, you must know that the nature of the flesh, of the body, the veins, the bones, has in it an innate force which heals wounds, thrusts and such like things.

Therefore, the surgeon should know that it is not he that heals, but the force in the body. If the physician thinks it is he that heals he deceives himself and does not understand his art. But that you

may know for what purpose you, the surgeon, exist, learn that it is to provide a shield and protection to nature in the injured part against enemies, so that these external foes may not retard, poison, nor spoil the force of nature, but that it may remain in its vital power and influence by the maintenance of such protection. Therefore, he who can protect and take good care of wounds is a good surgeon—*Paracelsus*.

THE BRIDGE OF LIFE

By MR C C FERGUSON,

*General Manager, The Great West Life
Assurance Company*

Winnipeg

It is a fact that there has been a noteworthy improvement in mortality, especially in the past quarter of a century, but the way this is frequently expressed is liable to occasion serious misconception. For instance, we are told that the duration of human life has been increasing as follows —

In the 17th and 18th centuries at the rate of four years per century,

In the first three-quarters of the last century by nine years per century,

In the last quarter by fourteen years per century,

And in the first quarter of this century by forty years per century

At this rate of progression we may expect that in a few more centuries people will live for at least a thousand years, thus restoring the golden prime of Methuselah—a vain hope, which I am sorry I cannot endorse!

The problem is how to express the improvement which has taken place, and this is not an easy task. It is difficult to avoid paradoxical, or seemingly contradictory, phrases, which tend to bewilderment rather than enlightenment. For instance, while the expectation of life in infancy may run from fifty-five to sixty years, the most probable year of death for human beings is the first year of life, and it is a fact that on the average a child of eight years will live for a longer time than a newly born babe. This latter seems very much like suggesting that a part of life is greater than the whole, whereas it really implies that infant mortality rates are very high. The high rates during early infancy diminish the infant's chance for longevity. We approach here the crux of the whole situation. In past generations, the wastage of infant life was appalling. It is still very great, but there has been a vast improvement during the past quarter of a century. So when people say that five, ten, or fifteen years have been added to the length of human life, they merely mean that infant mortality rates have been strikingly reduced. They do not, or at least they should not, imply that for adults there has been any similar addition to the span of life, because this is certainly not the case. There has been some improvement in the expectation of life at prac-

tically all ages, but the degree of improvement has been comparatively moderate except in early infancy.

It is not surprising that there is this improvement in mortality all through life when one remembers that certain diseases, such as small-pox, typhoid and diphtheria, once deadly, have now been practically eliminated. Tuberculosis is being successfully combatted, and, in general, great progress has been made, especially against diseases caused by parasitic microbes. Yet, there are some few people who still disbelieve in the existence of germs, and seek to remove their obvious manifestations by incantations, genuflections and contortions. On the other hand, modern civilization has invented new agencies to shorten human life. I refer to the automobile, the railway train, the aeroplane, explosives, chemicals and wood alcohol. Turning to the credit side again, we have now a much better chance of survival against violent death at the hands of outlaws and criminals. Perhaps I should except from this remark the residents of a certain city in the United States where, if King George did rule, there might be fewer murders.

As an example of improving mortality rates, I give below a Table showing the expectation of life for males, as found in England in the years 1911 and 1921 respectively.

Age	1911	1921
0	51 50 yrs	55 62 yrs
10	53 08 yrs	54 64 yrs
20	44 21 yrs	45 78 yrs
30	33 81 yrs	37 40 yrs
40	37 74 yrs	29 19 yrs
50	20 29 yrs	21 36 yrs
60	13 78 yrs	14 36 yrs
70	8 53 yrs	8 75 yrs
80	4 90 yrs	4 93 yrs
90	2 87 yrs	2 82 yrs

An inspection of this Table shows that the average infant of 1921 had a considerable advantage over the babe of 1911 in his probable length of life, but the Table further suggests that he soon loses the greater part of that advantage, so that at the age of 70 his prospects of further longevity will be very little better than those which face the septuagenarian of to-day. The statistics, therefore, do not so much emphasize for the modern babe the prospect of living to a ripe old age, but rather hold out a better promise that he will survive the dangers of weaning, they do not suggest, so much that he will survive many distant winters, but rather that he will have less immediate trouble from summer complaint. Centenarians are as rare

now as they were a century ago, so that the modernists have as yet no justification for translating "three score years and ten" into "a hundred"

It is not clear just what the Psalmist meant by quoting seventy years as the length of human life. I do not think that he was suggesting a basis on which actuaries could compute life-insurance premiums. Neither do I think that he had in mind the life-expectancy of an infant, or that he deduced his conclusions from any scientific study of the population statistics of his day. What he probably meant was that seventy years should be regarded as the average length of a well-rounded, normal life, not cut short prematurely by disease or injury. From this point of view his statement is correct. At least it is correct according to one of our modern mortality investigations, which shows that the average age at death of all persons who die after age of fifty is exactly seventy years.

Have I demonstrated my point? Is it clear that the cause of the recent improvement in mortality has been that a great many persons have been saved from premature death, especially during infancy and not that the human frame is taking on any greater inherent staying powers against the ordinary wear and tear of existence? There is absolutely no proof or indication that the period of a normal life (not cut short prematurely) is any greater now than it was a thousand years ago.

The struggle for existence goes on. Do we see in Death the stern warrior, in various panoply, bloody or anæmic, waging relentless war with life which, hoping merely to prolong the combat, now seems to be effecting its limited purpose, only to yield finally to its invincible foe? Or, do we picture the Grim Reaper, now more careful not to destroy the unripe crop, but taking as of yore and in like season his harvest of the golden grain? Or, do we think of the Wise Gardener who, relentless, in the present but beneficent in His ultimate purpose, thins out the fruit while yet green, but now leaves to mature a few more than in times past accorded with His judgment? At the same time, do not think that I am minimizing what has been accomplished. The prolongation of life, especially among the youthful, is a great achievement, a tribute to the efficiency of modern civilization.

I have compared the mortality rates based on population statistics of England, Scotland and the United States of America. Of these three countries, England appears to have the lowest mortality rates and Scotland the next lowest. It is possible that in Canada and Australia still lower rates prevail, but I have not the material at hand to state definitely.

In every population investigation, it is found that females have a greater expectation than males. On the other hand, males whose lives

are insured show lower mortality rates than females, while in connection with life annuities the reverse is the case. It almost seems to the life companies that a woman who buys an annuity straightway takes on immortality!

But the question remains how can the improvement in mortality be best expressed? Is there any appropriate index figure which will briefly tell the story? Certainly the expectation of life for the new-born babe is a misleading guide. Perhaps as good a method as any would be to use the expectation of life for age ten and in conjunction therewith note the probability of survival from birth to that age. This really involves the use of two index figures. The following table shows these index figures for the mortality of English males for the years 1911 and 1921.

	1911	1921
Probability of infant surviving 10 years	81.2 per cent	85.7 per cent
Expectation of life at age of 10	53.08 yrs	54.65 yrs

These figures, however, give no indication of the variations in the rate of mortality for particular ages. Such variations are wide, and the only strictly accurate method of comparing two mortality tables is to use about a hundred index figures, namely, the rate of mortality for each age of life.

Considering the expectation of life shown above for the age of 10, it would be possible to calculate a rate per centum for the gain in longevity, but I will not contribute to further misconception by calculating it. It would obviously be much less than the forty years referred to at the beginning of this paper, and it is very improbable that the gain recorded for the decade will be maintained in like proportion during the whole of the century.

It is an interesting speculation to estimate what is the maximum expectation of life that can be realized for the new-born infant. Using in this connection an imaginary mortality table, based on the more favourable population and insurance statistics available, and eliminating all excess mortality at infantile ages, I find that such maximum expectation would be sixty-five years. My prediction is that it will be a long time before this is generally realized.

The improvement in mortality is naturally of very great interest to life-insurance companies, but as insurances are practically never issued to infants (save in the form of savings contracts which are really not insurances), the improvement in infant mortality has had no effect on the prosperity of the business. Life insurance, has, however, benefited greatly by the improvement in adult mortality rates, but not to the extent that one might suppose who generalized from the improving life expectancies of infants.

The question is often asked why the companies do not lower the cost of insurance to the public considering the increasing profits they must be making in view of improved mortality. My answer is, first, that, as I have pointed out, these profits have not increased to the degree that the superficial observer might suppose, and, in the second place, I would reply that the cost of life insurance has been reduced considerably, so that it is now lower than it has ever been in previous history. Perhaps I may be permitted to ask the critic how many other lines of business there are which can make the same claim. It is true that there has not been much change in the average premium charged for participating insurance, but the profit refunds to the insured have been enormously increased, resulting in the noteworthy decrease in net cost of which I have been speaking. On the other hand, the rates for non-participating policies have been materially reduced, and I believe the reduction has been greater in degree than would have been justified solely by the decreasing mortality rates.

In discussing mortality statistics the term 'expectation of life' is always employed, but it may be stated, as one of the paradoxes of the subject, that actuaries do not use the expectation of life in calculating premium rates. For technical reasons, it would be incorrect to do so. They have to use a more intricate method, involving a consideration of the mortality rate for each year of life, and this tempts me to present to you a picture of human life, as the actuaries see it, and as it was described by Addison in his "Vision of Mirza."

'The bridge thou seest is human life, consider it attentively.' Upon a more leisurely survey of it, I found that it consisted of three score and ten entire arches, with several broken arches, which, added to those that were entire, made up the number about an hundred. As I was counting the arches, the Genius told me that this bridge consisted at first of a thousand arches, but a great flood swept away the rest, and left the bridge in the ruinous condition I now beheld it. 'But tell me further,' said he, 'what thou discoverest on it.' 'I see a multitude of people passing over it,' said I, 'and a black cloud hanging on each end of it.' As I looked more attentively I saw several of the passengers dropping through the bridge into the great tide that flowed underneath it, and upon further examination perceived that there were innumerable trap doors that lay concealed in the bridge, which the passengers no sooner trod upon but fell through them into the tide, and immediately disappeared. These hidden pitfalls were set very thick at the entrance of the bridge, so that throngs of people no sooner break through the cloud but many of them fell into them. They grew thinner towards the middle, but multiplied and lay closer together towards the end of the arches that were entire. There were indeed some persons, but their number was very small, that continued a kind of hobbling march of the broken arches, but fell through one after another, being quite tired and spent with so long a walk.

Observe, if you please how scientific, as well as artistic, is Addison's "Bridge of Human Life." He did not represent each individual as

walking out on the bridge until his expectancy was reached and then dropping off simultaneously with all others of his generation. On the contrary, he showed the infants perishing in large numbers, he showed a much lower mortality among those in robust youth, with increasing rates for later life. He accurately described the various diseases as "trap-doors" and "pit-falls" to prematurely catch the unwary or unfortunate. If Addison could return now, he would find that many of these trap-doors and pit-falls have been at least partially built up, and I imagine he would join with me and with you in expressing gratitude to those agencies and individuals which have been so diligent in the work of repair—to the colleges of medicine and science, to the doctors and nurses, to all the organizations that deal with public health and sanitation. The improvement has not come about fortuitously, it has been the result of study and effort of a high order. The wonder is that there are still some who will not give to science the credit she has fairly won, but who persist in their reliance on irrational remedies, which are really undermining the arches of the Bridge of Life, instead of strengthening or repairing them.

An Address

or

MATERNAL MORTALITY FROM PUERPERAL SEPSIS *†

By JAMES YOUNG, D.S.O., M.D., F.R.C.S.

*Physician, Edinburgh Royal Maternity
and Simpson Memorial Hospital,
Edinburgh*

It is unnecessary in these days to emphasize the tragic importance to the community of the large mortality amongst young women which is incurred yearly through childbearing and childbirth. In these islands the maternal death rate is about 4,000 each year, between 1911 and 1926 inclusive there were 66,421 deaths from these causes in England and Wales. Septic infection is by far the most important single cause.

This loss by death, however, is in some ways not the gravest consequence of child-bearing, for we have come to realize that, for each mother so lost, there are many more whose health is in varying degrees chronically undermined by the damage they have sustained in childbirth. Infection and mechanical damage thus acquired are amongst the main causes of the frequent chronic ill health which dates from childbirth. We can assess within accurate limits the loss by

* Abstract of an address communicated to the Edinburgh Obstetrical Society, May 9, 1928, (*Brit. M. J.*, 1928, 1, 967).

† Many of the statistical quotations are omitted for lack of space (Ed.)

death, but of the incidence of persisting invalidism of child-bearing origin we have no exact knowledge. We know with certainty, however, that many of the common gynaecological disorders, the uterine hæmorrhages, the leucorrhœas, the pelvic pains, the displacements, etc., and many general disturbances, debility, indigestion, neurasthenia, rheumatism, etc., are to be traced to the lesions of childbirth. It is probably not an over-statement to say that about 60 per cent of hospital gynaecology is a legacy from vitiated childbearing, and of this a very large part falls into the category of infection. Septic inflammation of the genital canal during labour or in the puerperium may, as a useful basis for analysis, be considered as falling into one or other of three clinical types according as it is caused by (1) contagion, (2) trauma, or (3) auto-infection.

In the case of *contagion* we are dealing with an invasion of the passages by a virulent septic micro-organism, which is introduced from without. Here, as in other infective diseases—for example, scarlet fever, erysipelas, typhoid, or tetanus—our etiological quest is dominated by the consideration of the nature, virulence, and source of the infecting microbe. This type of puerperal infection is seen in its simplest form when it occurs after a normal, easy labour, with an absence of trauma of the maternal passages, and in this category are to be classed the epidemic scourges of the maternity hospitals of a former day.

Puerperal sepsis due to *trauma* is, in its essential etiological features, entirely different from that caused by contagion. Here the factor which dominates the issue is a lacerating or contusing damage of the walls of the birth passages, and the source and nature of the infective organisms become a matter of comparatively secondary importance. By this is meant that it is the trauma of the soft parts that determines the risk of sepsis. The infecting microbes which can determine the infection in such a case are notoriously widespread in nature. They may be considered as being derived exogenously or endogenously, in either case they may conceivably consist of micro-organisms which only cause disease when settling in devitalized tissue. The point of clinical importance, however, is that these somewhat theoretical matters concerning the origin of the microbe are overshadowed by the vital issue of trauma.

The third clinical type of puerperal fever is that caused by *auto-infection*. Here the micro-organisms which set up the pelvic inflammation are, in some cases, present in the genital canal before labour begins—for example, in an infected cervix. In other cases they reach the genital passages from some distant source by direct spread or by implantation—for example, from the bowel—or they may travel by the blood stream from areas of focal infection in teeth, tonsils, etc. Auto-infection, like contagion, operates in its simplest form when it supervenes in a normal spontaneous birth in which there has

been a minimum of interference and trauma. Before we can hope to grapple with the menace of puerperal fever a knowledge of the manner and degree in which these three factors operate is necessary. Until we have this knowledge much of our effort must be largely haphazard.

AUTO-INFECTION

Within recent years many observers have attempted by this means to explain infection occurring in those spontaneous cases which have not been examined at any stage of labour. It is clear that, if operating in an appreciable ratio, it would go far to explain the persisting high death rate from sepsis despite the application of the aseptic principle. Victor Bonney and others have urged its importance with considerable force and plausibility, and its possible significance is referred to in the recently published report of the Committee appointed by the British Medical Association (*Supplement to the British Medical Journal*, April 28th, 1928, Appendix iv, p 165). Undoubted examples of autogenous infection can be cited, for instance, puerperal fever arising during scarlet fever, erysipelas, etc. A consideration of the available data, however, suggests that as a factor in the death rate autogenous invasion probably plays a minor part. Suggestive evidence may be found in an analysis of the records of many extensive maternity practices at the present day. The extern practice of the Edinburgh Maternity Hospital shows a consecutive series of about 5,000 spontaneous births with 2 deaths from sepsis, the extern department of the Birmingham General Hospital records 888 cases with an absence of sepsis mortality, whilst there is the record of 47,503 deliveries, both normal and abnormal, in the unselected practice of the East End Maternity Hospital in London with 5 deaths from sepsis, or 1 in 9,500. The practice of the Queen Victoria's Jubilee Institute midwives is likewise instructive. During 1927 there were 53,502 deliveries with 6 deaths from sepsis in normal spontaneous births, or 1 in 8,900 of the total. If we include all the deaths in this record of 53,502 cases which can directly or indirectly be attributed to sepsis, and including normal and abnormal cases, we get a maximum figure less than 0.5 per 1,000. To the production of this figure all causes have contributed. The fact which seems to emerge clearly from these data is that the very small sepsis rate in these large and unselected bodies of women is an argument against self-infection operating alone being an appreciable component of the sepsis death rate in the rest of the community. It is especially important that our ideas on this question be clarified, because much of the uncertainty and confusion in the minds of those who are anxiously seeking a remedy for the present state of affairs springs from the difficulty in assessing the true significance of this factor.

Much recent bacteriological research has been directed to the elucidation of these questions,

more especially in an attempt to relate the vaginal and cervical flora with the incidence of puerperal sepsis. As a result of this work we must now concede a comparatively frequent occurrence of streptococci in the genital passages of pregnant women, but, although it is established that puerperal infection is commonly caused by strains of streptococci, there is no evidence that the streptococci frequently present in the genital canal can play any part in initiating this infection. The fact of their frequent presence, combined with the rarity of puerperal sepsis in the absence of other factors which have a determining rôle, such as trauma, implies that this streptococcal flora possesses practically negligible primary virulent properties.

CONTAGION

Contagion is known to play a part in puerperal sepsis at the present day, as witness pelvic infection following contact with the virus of scarlet fever, or the epidemic deaths which occasionally occur in maternity homes and hospitals. To study the features of this type of infection satisfactorily, however, we have to turn to the records of the pre-Listerian lying-in hospitals. Epidemic waves of the disease were, as is well known, the scourge of these institutions. For example, in the large hospital at Vienna, out of 21,120 women delivered from 1840 to 1846, 2,260 died, or about 1 in every 10 mothers delivered perished, chiefly from puerperal fever. In 1774 at the Hôtel-Dieu, Paris, every patient attacked died—altogether about half the patients confined in the hospital.² The striking lesson for us is that, in these old hospitals, puerperal fever would seem to have been so predominantly a matter of contagion that other factors were largely negligible. I have been strongly impressed with this somewhat remarkable fact during a recent study of the records of the old Edinburgh Maternity Hospital. From 1823 to 1844, out of 3,906 women delivered in this hospital, 75 died from all causes. The records are not complete enough for an accurate differential analysis of the causes of death for this whole period, but in one of his striking papers on puerperal fever Sir James Young Simpson¹ gives accurate data for the period from 1823 to 1837, when there were 47 deaths among 2,890 women delivered, 36 out of these 47 deaths were, according to Simpson, due to puerperal fever. When we turn to the records we find that the distribution of these deaths is instructive. We discover that 30 occurred in three years, when obviously contagion was rife. On the other hand, during the four years 1826 to 1829 inclusive there were 821 successive births without a death. We may deduce from this that during this period of fifteen years, when contagion was eliminated, there was little or no mortality from puerperal fever.

The records of other hospitals exhibit the same facts.

The fact that contagion was the dominating

cause of puerperal fever in those days is brought out also by a study of the records of the outdoor practice of the hospitals. In this connection the records of the Edinburgh Maternity Hospital from 1826 onwards, which I have recently had an opportunity of studying, are instructive. Between 1826 and 1857 there were 15,144 successive deliveries with 61 deaths—that is, a rate of 4 in 1,000. The cause of death is given in 44, and in 19 it is stated as puerperal fever—that is, about 43 per cent. If we assume that this figure applies throughout the series the sepsis deaths would represent under 2 per 1,000 deliveries. I have shown that, in the outdoor department, there were considerable periods without any mortality from sepsis, clearly due to the chance absence of contagion. The same is true of the outdoor practice. Thus there is a record of 3,288 successive births during the nine years from 1839 to 1847 with no sepsis deaths. The elimination of this element brings the total death rate during this period down to 5 in 3,288, or about 1.5 per 1,000. These figures naturally challenge comparison with the practice of the art at the present time. Before any legitimate comparison is possible, however, it must be recognized that the above figures refer to deliveries and abortions, and do not include deaths from such complications of pregnancy as hyperemesis and ectopic gestation, which appear in the ordinary maternal mortality returns of the present day, and which constitute about 10 per cent of the deaths in the Registrar-General's Report for Scotland.

The limited figures just quoted support the belief that during the past hundred years there has been no depreciation in maternal mortality, and this is in accord with the national statistics. For Scotland the decennial mean figures from 1855 to 1914 are 4.9, 5.1, 5.2, 5.3, 4.6, and 5.6 per 1,000 births, and the mean for the period 1915 to 1922 is 6.2. Likewise the proportion of deaths from sepsis during this period has shown little change—namely, 1.7, 1.8, 2.0, 2.5, 1.9, 1.7, 1.7.

To realize the significance of these findings we must visualize the manner in which childbirth was managed in the pre-Listerian days and how this differed from our modern methods. The first fact of which we must remind ourselves is that our predecessors had no knowledge of aseptic or antiseptic procedure. It is abundantly clear that it is to this we must attribute in the main the ravages of puerperal contagion, for they examined freely during labour, and, in cases of retained placenta, they had no hesitation in introducing the hand into the uterus. Abdominal expression of the placenta by the Credé method did not, in point of fact, come into use till about 1867. The other important fact regarding the practice of those days is that it was based firmly upon the teaching of Harvey, Smellie, Hunter, Denman, and others, who insisted that child-bearing was a physiological process, which must be left to Nature, and which

was apt to be vitiated by interference on the part of the accoucheur. This was to be stringently withheld until Nature's effort had unmistakably failed. Instruments of any sort were the last refuge. Simpson, for example, in the Edinburgh Maternity Hospital, used the forceps in 1 in 472 labours, and other hospitals had a similar record.

These old records have a further bearing on the subject-matter of our discussion, for, as we know, there was little regard paid to the danger of repeated vaginal examination. Despite this, and the obvious and common contamination of the genital passages which must have then occurred, there was a negligible mortality from sepsis except where virulent contagion was present. This suggests that the microbes introduced by such contamination had little infectiveness in the case of labour conducted with a maximum regard to physiological needs.

The records of these pre-Listerian times would seem to suggest that, although contagion was a common cause of death, trauma was a factor which operated comparatively rarely, and this we must attribute to the principles which then underlay the practice of the art. I have shown that so strongly was this the case that at times the results obtained by our forefathers were such as compare favourably with the best practice of the present day.

It would clearly be to our advantage could we analyse the factors that stand behind the present high rate of sepsis as satisfactorily as is possible in these older records. Unfortunately in modern times the subject is hedged around with difficulties and uncertainties that make the study baffling in its complexity.

CONTAGION AS A FACTOR IN THE PRESENT SEPSIS DEATH RATE

How far contagion or trauma, or both combined, are responsible for the death rate from sepsis at the present time we have no accurate means of discovering. The massive sepsis of the pre-Listerian days, when surgical contagion repeatedly overwhelmed the surgical and maternity wards and often spread into extra-hospital practice, is no longer with us, and it would seem certain that the elimination of this virulent and spreading contagion must necessarily have led to a lessening of this contact factor in modern practice. Despite this, however, we know that contagion does still operate—as, for example, where the scarlatinal virus is transmitted to a parturient woman, or where two or more women are clearly infected from one common source. The exact extent to which infection so conveyed is responsible for modern sepsis is, however, more difficult to define than in the case of the older records. Whilst this is so, we are not altogether without evidence. The figures I have already quoted in connection with auto-infection are again of service here. In the outdoor practice of the Edinburgh Maternity Hospital, for example, during four years there have been about 5,000 normal deliveries with 2 deaths. During the

year 1927 there were 53,502 deliveries in the practice of the midwives of the Queen Victoria's Jubilee Institute in England and Wales with 6 deaths from sepsis in normal births—that is, 1 in 8,900 total deliveries, or about 0.1 in 1,000. This total figure refers, of course, to all cases, normal and abnormal. If we exclude the forceps cases we get a figure approximately equal to 1 in 8,000 or 0.12 in 1,000. This indicates the rarity of contagion in the practice of midwives, and when we remember that in England and Wales over 50 per cent and in Scotland over 30 per cent of the maternity service of the community is in their hands, we have ample reason for the belief that, in this proportion of the country's service at least, contagion is of comparatively minor importance. Then we have a record of 47,503 successive cases in the outdoor and indoor practice of the East End Maternity Hospital, with a total of 5 deaths from sepsis, or 1 in 9,500 cases. It is, of course, not necessary to conclude that all the sepsis deaths in these records are due to contagion. The figures are quoted with the object of indicating the maximum possible mortality from this cause when this is operating alone. It is not easy to conceive any reason why this small ratio of contagion should be appreciably different in the rest of the community not covered by these precise records. In other words, the above analysis leaves in one's mind the impression that contact infection, while it does admittedly still occasionally operate to maintain the incidence of fatal puerperal sepsis, is probably a factor of comparatively minor value, and that to explain the persistently high rate in modern practice we have to direct our attention to other factors.

CONTAGION IN PRESENT-DAY HOSPITALS

At the same time the magnificence of the era inaugurated by Lister is apt to blind us to the fact that even in the hospital system of our own times there are still perpetuated in some degree the risks with which our forefathers battled in vain. There is still intrinsic in it the danger incidental to the assembling of numbers of parturient women within four walls. The reality of this risk is at once apparent when we recall that, whilst the main practice of such hospitals is concerned with normal childbirth, it is also largely engaged in serving, and in attracting to itself, often from a wide district, the abnormal, which is often synonymous with the frankly or potentially infected case. This is especially true of the large central hospitals, where the fact of numbers naturally multiplies the risks. A study of this problem has long convinced me that these risks are by no means negligible. Even when the technique of the hospital is good, the risk of the leakage from infected to clean case can never be completely blocked, more especially at times when the hospital practice is working at high pressure.

In support of these contentions I may quote the figures of one well-known hospital, for which I am indebted to the registrar. During four

years, in 4,278 normal spontaneous deliveries there were 72 cases of puerperal fever with 5 deaths. In yet another well-known hospital during one year there were reported 11 instances of puerperal infection in spontaneous births with 3 cases in which the birth is described as quite normal. The report of another large hospital shows that, out of 27 deaths from puerperal infection in one year, there were 4 deaths in women in whom the birth was spontaneous and uncomplicated. These hospitals are all actively engaged in abnormal midwifery in addition to catering predominantly for the normal birth. The problem is thus seen to be a complicated one.

The admission, the examining, the labour rooms, and the wards of the two sets of cases must be rigidly isolated from one another, and the same rigid separation must apply to the nursing. The risk of patient-to-patient transmission is further lessened by the adoption of the small ward principle, especially for the abnormal delivery. In many instances we know that maternity hospital buildings are inadequate, and, in their present state, are unable to meet the demands which a rigid application of the modern ritual of prevention implies. I feel that, although the consideration of such questions introduces matters of some delicacy, it is urgent that they be reviewed in the frankest possible manner at this time, because as we all know, there is a strong advocacy in some quarters of an increase in maternity hospital accommodation as one means towards remedying puerperal mortality and morbidity. Whilst finding myself in sympathy with this attitude, I must admit that I consider any such widespread experiment as having elements of danger, except it be carried out with the most stringent regard to the safeguards I have mentioned. The exact proportion of the total sepsis death rate which this hospital contagion implies we have no means of determining. That, however, we may safely consider it as comparatively small is indicated by the meagre share of the total births which occur in hospital. The maternity hospital beds officially known by the Ministry of Health to exist in England and Wales number only 2,290 in 149 institutions (Janet Campbell, *Protection of Motherhood*, 1927, p. 64).

TRAUMA

I have already stated that the factors behind the persisting sepsis rate are complete. One example of this suggests itself to the mind. It is often urged that we have lost to parturient women the advantages of a century's progress because we have vitiated child-bearing by a too great recourse to instrumental delivery. It is true that interference with the natural process, by instrumental or other means, was in the old days employed at the most in only one out of several hundred cases, and that, even under the best conditions nowadays, such physiological child-bearing is only rarely found. Even in the case of the practice of the Queen Victoria's Jubilee midwives, who, it may be argued, deal with

the most normal class of case, the forceps deliveries number about 6 per cent of the total, and in the East End Maternity Hospital, where physiological childbirth is rigidly aimed at, the instrumental rate is over 2 per cent. Over the rest of the community we may safely conclude this rate is still higher. Faced by this indisputable evidence it is not surprising that many have urged that trauma is at the back of modern sepsis. It cannot be denied that there are cases—and every member of the staff of a maternity hospital can quote instances—in which unjustified interference has led to disaster. On the other hand, to argue on the basis of such individual cases—which usually spring from lack of experience and well-intentioned though over-anxious zeal—that trauma inflicted by malpraxis is the essential cause of the persisting death rate is to lose sight of other factors which have a wide-reaching significance.

One of these factors concerns the possible change in the fitness of women for child-bearing and childbirth as compared with their sisters a century ago. During this period there have been gross changes in the mode of life and feeding of the community. Moreover, we have to consider the possible and special bearing of rickets. It is not improbable that the increased protection of child life, which constitutes one of the most remarkable features of modern social hygiene, may have increased the proportion of those with skeletal defect who survive into adult life. As an obstetrician practising amongst the same class of women as those with whom Sir James Young Simpson had to deal nearly a century ago, I am convinced that the need for intervention on mechanical grounds is now greater than it was then, when forceps were employed only in 1 in every 472 cases.

Whilst it is thus probable that traumatization has played in recent times an increasingly important part in puerperal sepsis—and the data analysed earlier in this paper would seem by a process of exclusion to lead the evidence incriminatingly in this direction—it is at the same time not improbable that at the back of it there are some structural factors not wholly within our control, and therefore not wholly preventable by us as obstetricians. There are, however, many indications pointing towards a better and possible provision for the parturient woman if we are prepared to take advantage of them. The practical conclusion to which my studies have led me is that, whilst auto-infection can be largely displaced from the platform to which it has been raised by some, and whilst contagion likewise probably plays only a secondary part, to trauma from interference it would seem we have to ascribe the chief agency in the maintenance of sepsis, although we are not warranted in assuming that the main burden of responsibility is to be placed on the medical attendant.

The fact that, with a well-organized maternity service, a greatly diminished mortality rate is obtainable points clearly the way to progress,

and suggests that the immediate problem for the community is the provision of better machinery for bringing to the help of labouring women the knowledge we possess, rather than the pursuit of a mark-time policy which awaits the outcome of further research.

In support of this contention I would instance the experience of the Queen Victoria's Jubilee Institute, which last year had the splendid record of 53,000 deliveries with a mortality of 72, or 1.3 per 1,000. It is to be noted that these figures refer to the combined practice of midwife and doctor, for medical practitioners were called in to the aid of the midwife in 25 per cent of the cases. It is a very successful and encouraging example of team work. The midwife's task is only made possible when it is united to the knowledge that she has the doctor behind her in case of need, whilst, on the other hand, the fact that the routine management of the practice is in the hands of the midwife makes for the possibility of a more physiological attendance of the normal case than is to be expected from the practitioner, with whom midwifery is often a disturbing item in the course of a busy day interspersed with urgent calls, and from whom, moreover, regardless of every other consideration, there is too often demanded a speedy termination of labour. It may be argued that the small death rate in this large practice is dependent upon the fact that the midwives' cases are to some extent selected. This is not denied, and that this selection is not inconsiderable is suggested by the very low death rate in the series from puerperal convulsions and albuminuria—from 0.1 to 0.2 per 1,000, as contrasted with a death rate over the rest of the community of from 0.6 to 0.8 per 1,000. Making every allowance, however, for these facts the record is full of encouragement, and points to the advantages to be obtained from a wider extension of the midwife-doctor system.

The signal advantages of such combination are even more convincingly demonstrated by such an institution as the East End Maternity Hospital in London, where the bulk of the cases are conducted by midwives, and abnormal cases are treated by medical practitioners on the honorary staff. This institution conducts over 2,000 cases yearly, about half being in the hospital. There is a well-organized ante-natal system, and the forceps rate is under 3 per cent. Despite the fact that the practice is amongst the very poor, and that it is practically unselected, it has a mortality rate standing at a little over 1 per 1,000 cases. For four years, in a total of about 9,000 cases, it sank to the extremely low level of 0.67 per 1,000. Sepsis is practically eliminated from this practice, and there can be little doubt that this is due mainly to the excellent administration, the careful supervision, and the low instrumental rate.

It is to be specially observed that the admirable results obtained in the case of these extensive practices flow entirely from the method and

machinery employed. There is installed by comparatively simple means a system by which—and this is especially noteworthy in such an institution as the East End Maternity Hospital—the physiological management of labour is encouraged, the abnormal case is seen betimes, and difficulty and danger are thereby anticipated and prevented. The record of this institution and its almost complete freedom from sepsis is one of the most cogent arguments in support of the contention that the dominating factor behind sepsis in ordinary midwifery is trauma. So remarkably successful has this hospital been in its effort to expel from its doors not only sepsis, but also the other complications of labour and the puerperium—for example, eclampsia—that we might at first sight feel ourselves compelled to attribute the result to some unduly favourable circumstance in the material of their practice. Against this, however, it may be urged that the official records show that the death rates of the communities in which this hospital carries on its work are several times greater than that exhibited by the indoor and outdoor practice of this institution.

It cannot, I believe, be denied that the evidence furnished by an enlightened and critical analysis of all the various forms of maternity effort we have reviewed goes to support the contention of Fairbairn and others that "a country's maternity service is best built on the foundation of a service of midwives with medical help in difficult cases." Before this ideal can be universally realized much must be done in the way of education of the public and in the reorganization of the present machinery of practice. Doctors can do a great deal in both directions, and there is ample evidence to hand that in these objects they can count on the help of the central and local authorities. The problem in any area can only be satisfactorily dealt with by strenuous local effort.

The high death rate in some areas invites the suggestion that on occasion the subject may become eminently a matter for the active interest and participation of the local body.

CONCLUSIONS

- 1 Autogenous infection is a minor primary cause of fatal puerperal sepsis.

- 2 Contagion is probably of comparatively secondary importance. The well-established risks of contact infection in hospitals call for care in the extension of the hospital system of maternity service.

- 3 There is evidence that trauma is the most important cause of the death rate from sepsis. This is not entirely a problem involving the medical attendant, it has implications of a wider nature.

- 4 The immediate need is an improved machinery for maternity practice based on a midwife-doctor combination. From the standpoint of immediate policy the importance of this

overshadows all other considerations—for example, “research”—and there is reason for the hope that by this means alone a lessening of the death rate is possible

5 Improved education of the public, the midwife, and the student, and the assistance of the central and local authority, are all necessary for the creation and working of a satisfactory machine

DR FORDYCE, in the discussion following this paper, regarded the question of segregation of confinement cases in hospitals as an important one, and doubted whether it was advisable for normal cases to be confined in hospitals where there was only a limited amount of space. He thought that forceps delivery in selected cases prevented the trauma which might otherwise be caused by a very delayed labour

PROFESSOR HENDRY referred to three cases of pyrexia due to extraneous origins—namely, infective rhinitis, commencing whitlow, and a septic wound on the skin of the patient's husband, these showed the importance of contagion. He supported very strongly Dr Young's principle of separate accommodation in maternity hospitals for cases sent in after intervention outside

DR MILLER showed by statistics of the Royal Maternity Hospital that the incidence of pyrexia in patients delivered instrumentally was much larger than in those whose delivery had been spontaneous. He had found a marked variation in the bactericidal power of the blood in pregnant women, which might explain the variation in individual susceptibility to infection

DR J M BOWIE regarded trauma as of great importance in puerperal sepsis. He thought that the whole machinery of maternity service in this country needed overhauling. Reorganization might be effected in two ways (1) by the present system of trained midwives working alone in normal cases and assisted by doctors in difficult cases, or (2) since midwifery work appealed to many doctors a new race of specialists might rise, who would confine themselves to it

THE PRESIDENT thought that hæmolytic streptococci might be rendered temporarily inert by the normal vaginal secretion, but in certain circumstances they might regain their hæmolytic action. He urged the segregation of complicated cases, but to do this a large hospital was required. He did not think that trauma was only due to instrumental intervention, since normal labours were often associated with very severe trauma. He considered the co-operation of midwives and medical practitioners an excellent practice

THE FOUNDER OF THE RED CROSS

In connection with the centenary of the birth of Henri Dunant, the founder of the Red Cross, which occurred on May 8th of this year, the Canadian Red Cross proposed a competition in editorials on his life and work and his influence in promoting humanitarian standards and service first in war and now in peace. His idea, from which the Red Cross sprang, not only produced a very great improvement in the care provided for sick and wounded soldiers, but has also resulted in a world-wide peace-time organization for the improvement of health and the mitigation of suffering

A committee of well known writers made the awards. The following editorial by Mr H B Christie in *The Expositor* of Brantford, Ontario, won one of the prizes among the dailies. The celebration of Henri Dunant's birth and work took place in one form or another in fifty-four countries [Ed]

“The vision of the young Swiss philanthropist, Henri Dunant, gave to mankind one of the most chivalrous and beneficent organizations in the history of civilization, the Red Cross. In the ultimate working out of his ideal, he made an extraordinary contribution to the advancement of the social welfare of the world. Hence the Red Cross Societies throughout fifty-nine nations are celebrating to-day the centenary of his birth which took place on May 8, 1828. It is probable that Dunant derived the inspiration for his work from the heroic mission of Florence Nightingale, who, impelled by the revelation of the terrible conditions prevailing on the battlefields and in the hospitals of the Crimea, organized a band of devoted nurses to care for the wounded and dying soldiers, to supply their necessities, relieve their sufferings, and comfort them by a ministry of love and kindness

The event which stirred the sympathies of Dunant, and aroused him to action, was the agony and suffering which he witnessed as a youth, thirty-one years of age, at the bloody battlefield of Solferino, on the plains of Lombardy in 1859, one of the most sanguinary conflicts of history. In this battle the allied armies of France and Sardinia, to the number of 150,000, superbly led by Napoleon III, Victor Emmanuel and Marshall MacMahon, utterly routed the Austrian army, which numbered upwards of 175,000, under the personal command of the Emperor Francis Joseph. The slaughter was appalling. The battlefield was strewn with 40,000 killed and wounded soldiers, and the ghastly scenes of suffering and death witnessed by Dunant, as the terrible conflict ebbed and surged through sixteen long hours, as the dead and dying were trampled by the advancing armies, crushed by galloping artillery, ruthlessly trodden down by the iron hoofs in fierce cavalry charges, made an unforgettable impression on his mind and he wrote the book, ‘A Souvenir of Solferino,’

in which he vividly portrayed the gruesome horrors of the battlefield

His purpose in portraying these scenes of horror and suffering, in which the wounded and dying were left without adequate medical attention and nursing, was to call the attention of the civilized world to the cruel inhumanities of war, and to cause something to be done for the relief of the wounded and suffering soldiers. "Would it not be possible," asked, "to found and organize in all civilized countries permanent societies of volunteers which, in time of war, would render succor to the wounded without distinction of nationality?" Out of this suggestion came the noble and chivalrous philanthropic organization known as the Red Cross.

The idea was developed by Monsieur Gustave Moynier, president of the Society of Public Utility in Geneva and a jurist of international repute. Monsieur Moynier organized a committee of five to carry out Dunant's suggestion. This committee invited the governments of Europe, together with noted military, medical and philanthropic personages, to attend an international convention in Geneva on October 26, 1863. The convention was attended by thirty-six delegates, representing fourteen nations, and six charitable and benevolent associations. As a result the Swiss government called an official convention, which assembled in Geneva the following year. On August 22, 1864, what is known as the Geneva Convention, was signed by the delegates of twelve European nations, whereby, under the terms of the agreement, hospitals, officials of the sanitary service, volunteer nurses, inhabitants of the country aiding the wounded soldiers, and even the wounded soldiers themselves, were declared to be neutral. The terms of this convention were extended to naval warfare by The Hague convention of 1899. The Geneva convention was revised and replaced by the Washington convention of 1906.

Thus was brought into existence this great philanthropic organization, which was designed to supplement the medical and sanitary services of the armies by trained volunteer societies, and to minister relief in war, epidemics, famines, floods and disasters of every kind. It has been an incalculable blessing to humanity, and on the occasion of many conspicuous catastrophes afforded relief to stricken and suffering humanity. During the Michigan fires, in 1881, in the yellow fever epidemic in Florida, in 1888, in the Johnstown flood, in 1889, in the terrible Russian famine, in 1891, in the Armenian massacre, in 1896, in the Galveston disaster, in 1900, in the Mont Pelee eruption, in 1902, in the San Francisco earthquake, in 1906, during the terrible

earthquake in Japan, in 1925, in which 99,331 were killed, 103,733 injured, and 43,746 were missing, and on many similar occurrences, the Red Cross rendered heroic and faithful service, thereby vindicating its claim to be one of the greatest humanitarian agencies in the world. It reached its climax in the services rendered to the various nations in the Great War, and in numerous calamities of plague, famine and pestilence which occurred in Europe after its termination. It performed invaluable services in regard to prisoners of war, in the identification of missing men, in furnishing information of every possible kind, in the distressing problems of internment and deportation of civilians, hospital staffs, hostages, and refugees, in the repatriation of families in the invaded and devastated areas, and in ministering to the necessities of the homeless, sick and suffering in the plague stricken districts of Europe.

Perhaps the chief glory of the Red Cross has been the extension and adaptation of its work, under the Covenant of the League of Nations, to the needs of the world in times of peace, such as the improvement of health, the prevention and eradication of disease, and the amelioration of suffering wherever it is found. In pursuance of this policy the Canadian Red Cross has cared for the needs of ex-service men, and has established nurseries at the seaports where, during 1927, help and comforts were provided for 30,000 new Canadians. Classes were conducted in home nursing for 12,000 women and girls, and hospitals and nursing stations were maintained in pioneer settlements, ministering to the needs of an extensive population. It has provided relief in disasters such as the Northern Ontario conflagration and the Cochrane epidemic, promoted measures for the public health and distributed large quantities of instructive literature. Moreover, it has introduced the Junior Red Cross into the schools of Canada, whereby, in five thousand classrooms, 140,000 young Canadians are given instruction in healthful living. It has provided treatment for 5,000 crippled children, and befriended the unfortunate in innumerable ways. In carrying on this beneficent work the Canadian Red Cross has expended \$7,000,000 and exhausted its treasury, but it has established its claim to the generous support of the people of Canada as a national institution of a philanthropic character, that knows no distinctions in its sympathetic and helpful service. The Red Cross, in carrying on its ministry to suffering humanity, is an exemplification of Him who went about doing good, and who said "It is more blessed to give than to receive."

The name "antimony", dating from the 13th century, has an interest all its own. One Basil Valentine was called on to treat a community of monks, and used a drug, then known as stibium, for

the purpose. The monks died, and the name antimony was born. The French original and present day word being "antimoine" from "anti moine" which in English is "anti monk."

Men and Books

THEORIES ABOUT THE MOVEMENT
OF THE BLOOD WHICH WERE HELD
BEFORE HARVEY

BY THE ASSOCIATE EDITOR

Montreal

The year 1628 marks the beginning of a new epoch in the history of medicine, for it was in that year that William Harvey, a London physician, published a book, small in size and humble in appearance, but great in matter—*Exercitatio Anatomica de Motu Cordis et San- guinis in Animalibus*. Here, for the first time in recorded history, a definite problem, dealing with an all-important function of the animal body, was attacked on the experimental side, under a definite and logical plan. The work is entirely modern in spirit, and is carried to an almost flawless conclusion.

It should be pointed out at the outset, to prevent misunderstanding, that Harvey did not discover that the blood *moved*—this was known to Aristotle and Galen—but he did discover why it moved and how it moved, and this at a time when the anatomists had not freed themselves from the domination of Galen. To appreciate fully Harvey's great contribution to physiology, and, indeed, to science generally, something should be known about the development of the notions current in regard to the movement of the blood and its function.

Aristotle considered the heart to be the central organ controlling the blood flow. It is the seat of vitality, the fount of the blood, the place where the blood is finally elaborated and imbued with animal heat. The blood is contained in the heart and vessels as in a vase, hence the term "vessel." He taught, farther, that the nutriment oozes through the walls of the bloodvessels and the various passages "like water in unbaked pottery," to use his apt comparison. Aristotle did not distinguish between arteries and veins. He calls them both "phlebes" ($\phi\lambda\epsilon\beta\epsilon\varsigma$). The vena cava is the great vessel, the aorta, the smaller, and both contain blood. He did not use the term "arteria" for either of them. There is no movement of the blood from the heart to the vessels, in the sense of an obvious current, but the blood is continually being absorbed by the substance of the body, and as continually being renewed by absorption of the products of digestion, the mesenteric vessels taking up food much as plants take it up through their roots. The "pneuma" or "spiritus" is obtained from the lungs and is distributed to the heart by the pulmonary vessels, one to the right, and one to the left. The vessels in the lungs absorb the "pneuma" by mutual contact with the branches of the trachea. In Aristotle's view,

the pulsation of the heart and vessels is a sort of ebullition by which the liquids are inflated by the vital heat. Cooling is brought about by the "pneuma," which is taken in by the lungs and brought to the heart. It is worth noting that the trachea is called $\alpha\rho\eta\rho\iota\alpha$ (arteria) both by Aristotle and Hippocrates. It is the *air-tube* carrying the breath through the lungs.

Coming now to the Alexandrines, one of the leading representatives of their school, Praxagoras, discovered that it is the arteries that pulsate, but he was responsible for the great error that the veins only contain blood, the arteries, air. Observing that the arteries after death are usually empty, Praxagoras concluded that during life they are filled with an aeriform fluid, a kind of pneuma, to which the pulsation is due. Consequently, the word "arteria," already applied to the trachea as an air-containing tube, became attached to the arteries. The trachea, on account of its rough and uneven surface, was called $\alpha\rho\eta\rho\iota\alpha \rho\alpha\sigma\epsilon\iota\alpha$ (arteria tracheia), that is the "rough air-tube." The French still call it "trachée-artère." Another great Alexandrine, Erasistratus, still farther elaborated the doctrine of the "pneuma," one form of which, he thought, comes from the inspired air, passes to the left side of the heart, and is distributed to the arteries. This is the cause of the heart-beat and the source of the innate heat of the body. It maintains the processes of digestion and nutrition. Erasistratus called it the "vital spirit." The other, the "animal spirit," is manufactured in the brain, chiefly in the ventricles, and is carried by the nerves to all parts of the body, thus endowing the animal with life and motion and perception. Thus, a fundamental distinction was made early between two sets of organs and two corresponding sets of functions. The vascular system, comprising the heart, vessels, and abdominal organs, is governed by the vital spirit, in the nervous system is elaborated the animal spirit, which controls motion and the general and special senses.

These teachings went almost unquestioned until well into the eighteenth century. Even now, we sometimes speak of "high" and "low" spirits, when we do we unconsciously reflect the views of the great Alexandrine.

Galen, four or five hundred years later, knew much about the movement of the heart, the pulsation of the arteries, and the action of the valves. He refuted by experiment the error that the arteries contain air and not blood. He tied a cord above and below a length of artery in the living animal and, cutting out the section, found, of course, that blood and not air was present inside.

Galen's conception ran something like this. There are two kinds of blood. One of these,

contained in the venous system, is dark and thick, and serves for the general nutrition of the body. This system starts from the liver, the central organ of nutrition and sanguification. From the portal system the products of digestion are absorbed from the stomach and bowels. From the liver come the *venæ cavæ*, one supplying the head and arms, the other the lower extremities. Springing from the right side of the heart is a branch corresponding to the pulmonary artery, which carries the blood to the lungs. This is the closed venous system. There is another, the arterial system, containing a thinner, brighter, and warmer blood, characterized by an abundance of vital spirits. Warmed in the ventricles it distributes the vital heat to all parts of the body. Both systems are closed, and communicate with each other *only through pores or perforations in the septum of the heart*.

One can hardly understand how Galen failed to discover the *circulation* of the blood. He knew that the pulsatile force is inherent in the walls of the heart, he knew that the systole drives blood out from, and that the diastole sucks blood into, the cavities of the heart, he knew that the valves of the heart determine the direction by which the blood enters and leaves the organ. But he seems to have been obsessed with the idea that the heart is a "fireplace," from which is derived the innate heat of the body. He did not grasp, evidently, that, instead, it is a "pump" for driving and distributing the blood. "How the body became such a 'fiery dragon,'" as Sir Clifford Allbutt phrased it, is sufficiently remarkable, and was never explained. His notion seems to have been that there is a sort of tidal movement in both systems, and yet, curiously enough, he sometimes makes use of expressions, in speaking of the venous system, singularly like ours. He calls it "a conduit full of blood, with a multitude of canals large and small running out from it and distributing blood to all parts of the body." The method of nutrition he compares to irrigating canals and gardens, with a wonderful dispensation of nature that they should lack "neither a sufficient quantity of blood for absorption, nor be overloaded at any time with an excessive supply."

Galen's views held sway, with all the weight of authority, until the time of Harvey. One step was made in advance, however, by Michael Servetus in 1553, when he described very accurately the lesser circulation in the lungs, in his *Christianismi Restitutio*. His immortal fellow-student Vesalius apparently was unaware of his work, for he accepted, at least at first (1543), Galen's dictum as to the porosity of the cardiac septum. That Vesalius had his doubts, however, is indicated in the second edition of his *De Fabrica* (1555), where he states that, in spite of the authority of the Prince of Physicians, he cannot see how the smallest quantity of blood can pass through so dense a muscular partition. It is singular how tenacious of life this doctrine of the porosity of the septum was, for many

years after, we find Harvey assuring Professor Riolanus, of Paris, who had his scruples, that "if only you will pour water into the right heart, and tie all vessels going to and from the lungs, not one drop will get into the left ventricle."

Lake Servetus, Colombo, also, believed in a lesser pulmonary circulation, but was so far astray as to deny that the heart is a muscular organ.

Finally, Cesalpinus, for whom has been claimed by his countrymen the honour of the discovery of the circulation of the blood before Harvey, is considered by Osler to be a simple Galenist. Cesalpinus believed, like all his contemporaries, that the blood was distributed through the body, for its nourishment, by the *vena cava* and its branches. But, to discuss the merits of the controversy would lead us too far afield.

And now William Harvey comes upon the stage.

WILLIAM HARVEY*

By HERMANN M. ROBERTSON, CBE, MD,
CM, MRCS (ENG), FRCS (EDN),
LRCP (LOND), FACS

Victoria

William Harvey the discoverer of the circulation of the blood, was born on April 1, 1578, at Folkestone, and died at Roehampton June 3, 1657. His preliminary education was probably carried on in Folkestone, where he learned the rudiments of knowledge and gained his first acquaintance with Latin. He went to the King's School, Canterbury, for five years, no doubt going home for the holidays, some of which must have been spent in watching the constant transport of troops to Spain and Portugal, which was so noticeable a feature of the Cinque Ports during the latter years of the life of Queen Elizabeth. His schooling ended, Harvey entered at once, as an ordinary student, at Caius College, Cambridge.

The choice of this College seems to show that he was already destined by his father to follow the medical profession. His habits of minute observation, his fondness for dissection, and his love of comparative anatomy, had probably shown the bias of his mind from his earliest years.

Dr Caius, in addition to his knowledge of Greek, may have been said to have introduced the study of practical anatomy into England. His influence obtained for the College the grant of a charter in the sixth year of the reign of Queen Elizabeth, by which the Master and Fellows were allowed to take annually the bodies of two criminals condemned to death and executed in Cambridge or its castle, free of all charges, to be used for the purposes of dissection. Unfortunately, no record has been kept as to the

*An address delivered before the Victoria Medical Society on May 18th, 1928, on the occasion of the Harvey Tercentenary Celebration.

use which the College made of this privilege, nor is there any means of ascertaining whether Harvey did more than follow the ordinary course pursued by students until he graduated as a Bachelor of Arts in 1597. His education, in all probability, had been wholly general thus far, consisting of a sound knowledge of Greek, a very thorough acquaintance with Latin, and some learning in dialectics and physics.

He now began his more strictly professional studies, and the year after he had taken his Arts degree at Cambridge found him travelling from France and Germany towards Italy, where he was to study the sciences more nearly akin to medicine, as well as medicine itself.

Harvey was attracted to Padua, and many reasons probably influenced him in his choice. The university was specially renowned for its anatomical school, rendered famous by the labours of Vesalius, the first and greatest of modern anatomists, and the work of his successor, Fabricius, one of the most honoured and learned teachers of his day. Carus had lectured on Greek in Padua, and some connection between his college at Cambridge and his old University may still have been maintained. The fame of Fabricius and his school was no doubt the chief reason which led Harvey to Padua, but there was an additional reason which caused his friends cheerfully to concur in his resolve. Padua was the university town of Venice, and the tolerance which it enjoyed under the protection of the great commercial republic rendered it a much safer place of residence for a Protestant than any of the German universities or any of its fellows in Italy.

Fabricius was more than a teacher to Harvey, for a fast friendship seems to have sprung up between master and pupil. At this time a man of sixty-one years (he died at the age of eighty-two), he was engaged during Harvey's residence in Padua in perfecting his knowledge of the valves of the veins. The valves had been known and described by Sylvius (1478-1555), that old miser who warmed himself in the depth of a Parisian winter by playing ball against the wall of his room rather than be at the expense of a fire. The work of Sylvius had fallen into oblivion, but Fabricius rediscovered the valves in 1574. His observations were not published until 1603, when they appeared in a small treatise—*De venarum ostiis*. There is no doubt that he demonstrated their existence to his class, and Harvey knew of the treatise, though it was published a year after his return to England.

Now, when we consider Harvey's work, it all appears to be a continuation and an amplification of that done by Fabricius. Both were intensely interested in the phenomena of development, both wrote upon the structure and function of the skin, both studied the anatomy of heart, lungs and blood vessels, and both wrote a treatise *de motu locali*. Harvey's youth, his comparative freedom from the trammels of authority, and his more logical mind, enabled him to outstrip

his master and to avoid the errors into which he had fallen. This advance is particularly well seen in connection with the valves of the veins. Fabricius taught that their purpose was to prevent over-distension of the vessels when the blood passed from the larger into the smaller veins (a double error), whilst they were not needed in the arteries because the blood was always in a state of ebb and flow. It was left to Harvey to point out their true use, and to indicate their importance as an anatomical proof of the circulation of the blood.

Harvey graduated as Doctor of Medicine at Padua in 1602, and the eulogistic terms in which his diploma is couched leave no doubt that his abilities had made a deep impression upon the minds of his teachers. The diploma was presented to the College of Physicians of London on Sept. 30th, 1766, and is dated April 25th, 1602. It further states that he conducted himself so wonderfully in the examination, and had shown such skill, memory and learning, that he had far surpassed even the great hopes which his examiners had formed of him.

Armed with so splendid a testimonial, Harvey must have returned at once to England, for he obtained the degree of Doctor of Medicine from the University of Cambridge in the same year, when it appears also, that he took a house in London, in the parish of St Martin's, and lost no time in attaching himself to the College of Physicians. This body had the sole right of licensing physicians to practice in London and within seven miles of the city, and he was admitted a licentiate of the College on October 5, 1604. A few weeks after this he married Elizabeth Browne, daughter of Dr Lancelot Browne, physician to Queen Elizabeth and to James I. Dr Browne died the year following his daughter's marriage. Harvey's union was childless, and we know nothing of Mrs Harvey, except that she died before her husband.

On June 5, 1607, Harvey was elected a Fellow of the College of Physicians, and immediately attached himself to St Bartholomew's Hospital.

Until the year 1745 the teaching of anatomy in England was vested in a few corporate bodies, and private teaching was discouraged in every possible way, even by fine and imprisonment. The College of Physicians and the Barber-Surgeons' Company had a monopoly of the anatomical teaching in London. Subjects were difficult to procure, and dissecting came to be looked upon as part of the legal process so inseparably connected with the death penalty for crime that it was almost impossible to obtain even a body of a "stranger" for anatomical purposes. The executions in London were witnessed by great crowds, who often sided with the friends of the felons and rendered it impossible for the body to be taken away for dissection. A Charter of James I enlarged their powers by allowing the College of Physicians to take annually the bodies of six felons executed in London, Middlesex or Surrey.

Little is known in detail of the manner in which Anatomy was taught by the College of Physicians, but it appears to have been carried out practically in a series of demonstrations upon a body. As there was no means of preserving a subject it had to be by a general survey, rather than in detail. A single body was dissected to show the muscles (this was the muscular lecture), another to show the bones (the osteological lecture), another to show the parts within the head, chest and abdomen (the visceral lecture). The lecturer for the various parts was not always the same, though great teachers, like Reid and Harvey, gave a course upon each subject.

The Lumleian Lecture was on Surgery, established at a cost of forty pounds by two notable men, Lord Lumley in Essex, and Dr Caldwell in Derbyshire. The lecturer was appointed for life, and its subjects were so arranged that they recurred in cycles.

Harvey, in all probability, began to lecture at once upon surgery as the more theoretical portion of his subject, but it was not until April, 1616, that he gave his first anatomical lecture. It was a visceral lecture for the terms of the bequest required that it should be upon the inward parts. He was only thirty-seven years of age at this time, a man of the lowest stature, round-faced. His eyes were small, round, and very black, his hair as black as a raven and curling, his utterance was rapid and he was given to gesture. When discoursing with anyone he unconsciously played with the handle of a small dagger he wore by his side.

The manuscript of Harvey's first course of lectures is now in the British Museum. The notes of his visceral lecture are of especial value to us, though they are a mere skeleton of the course. Fortunately, they deal with the thorax and its contents, so that they show us the exact point which he had reached in connection with his great discovery of the blood and the true function of the heart. Harvey was so good a Latin scholar, and during his stay in Italy had acquired such a perfect colloquial knowledge of the language, that it is clear that he thought with equal facility in Latin or in English. He used many abbreviations, and whole sentences are written in a mixture of Latin and English. The first set of notes deal with the outside of the body, and the abdomen and its contents, the second portion contains an account of the chest and its contents, whilst the third portion is devoted to a consideration of the head with the brain and its nerves.

After a full discussion of the situation and functions of the various parts of the abdominal viscera, he passes on to the thorax and enunciates his memorable discovery in these remarkable words,

"It is plain from the structure of the heart that the blood is passed continuously through the lungs to the aorta as by the two clacks of a water bellows to raise water. It is shown by the application of a ligature that the passage of the blood is from the arteries into the veins. Whence it follows that the movement of the blood is constantly

in a circle, and is brought about by the beat of the heart. It is a question therefore whether this is for the sake of nourishment or rather for the preservation of the blood and the limbs by the communication of heat, the blood cooled by warming the limbs being in turn warmed by the heart."

Here the notes on the heart end abruptly, and Harvey passes on to consider the lungs. These few sentences, however, show that he had discovered the circulation, and that though he delayed for twelve years to make his results public he was unable to add any important fact in the interval. The College of Physicians still preserve an interesting memorial of this portion of Harvey's Lumleian Lectures. It consists in a series of six dissections of the blood vessels and nerves of the human body, which are traditionally reported to have been made by Harvey himself. The dissections are displayed upon six boards, the size of the human body, and they exhibit the complete system of the blood vessels separated from the other parts so as to form diagrams of the circulatory apparatus. They have been made with such care that one of the series still shows the semilunar valves at the beginning of the aorta.

Harvey continued his Lumleian Lectures year by year, but we know nothing more of them until 1627, when he delivered a series of lectures upon the anatomy and physiology of the human body, more especially of the arm and leg, with a description of the veins, arteries and nerves of these parts.

On February 3, 1618, Harvey was appointed Physician-Extraordinary to James I, or, in the language of his time, "The King, as a mark of his singular favour, granted him leave to consult with his ordinary physicians as to his Majesty's health," and at the same time he promised him the post of a Physician-in-Ordinary, so soon as one should become vacant. This promise he was unable to fulfill, but it was redeemed by his son, Charles I, who appointed Harvey a Physician-in-Ordinary in 1631 and remained his friend through life.

Besides being physician to the household of the king, he seems to have held similar positions in the households of some of the most distinguished nobles and men of eminence. In the year 1613 he was elected a Censor in the College of Physicians. The Censors were four Fellows of the College appointed annually, "with power to supervise, watch, correct, and govern" those who practised physic in London or within the statutory seven miles, whether members of the College or not. They were empowered to visit the shops of the apothecaries to "search, survey, and prove whether the medicines, wares, drugs, or any thing or things, whatsoever such shops contained and belonging to the art and mystery of an apothecary be wholesome, meet and fit for the cure, health and ease of his Majesty's subjects."

On December 23, 1627, he was appointed to the still more important office of the "Elect." The "Elects" were eight in number. They

were chosen from the most cunning and expert of men of the faculty of London. It was their duty, once a year, to select one of their number to fill the office of President, to appoint a Board of Examiners for those who desired to practise physic throughout England. These examinations were conducted at the house of the President, where on December 9, 1629, Harvey examined and approved Dr James Primrose, Professor of Anatomy of Paris, who soon became the most malignant opponent of his teaching.

Early in 1633 Harvey received the commands of Charles I to attend him on his journey to Scotland. Charles' tour in Scotland was fraught with the most momentous consequences, both to himself and to his kingdom. Harvey must have been in close attendance upon the King during the whole of his stay, but he probably interested himself very little in the proceedings of the Court, or in the hot discussions between the rival sects around him. We know, indeed, that he was thinking about the method by which a chick is formed within the egg, and that to solve the point he paid a visit to the Bass Rock.

The year 1645 marks the period of Harvey's severance from the Court and of his practical retirement from public life. He was now 68, a martyr to gout, childless, and suffering under a series of heavy bereavements, and he can have had little heart to re-enter upon an active professional life in London. Harvey returned to London after the surrender of Oxford, and he was succeeded as reader of the anatomical lectures by Dr Scarborough, who was elected on October 8, 1649, by the company of Barber-Surgeons of London. Dr Scarborough was knighted on August 15, 1669, and his friendship with Harvey commenced at Oxford and continued unabated until the end of his patron's life, and when, on July 28, 1656, Harvey presented to the College of Physicians the title-deeds of his paternal estate in Kent and resigned his Lumleian lectureship, the office was transferred to Charles Scarborough. In his will Harvey makes affectionate mention of his friend, and bequeaths to him his surgical instruments and his velvet gown, so that literally, as well as metaphorically, Harvey's mantle fell upon Sir Charles Scarborough, and he nobly sustained the charge, great as it was.

Dr Ent has left a striking picture of the old man at Christmas, 1650, nearly a year after the execution of the King. He states that "Harvey lived not far from the city, where he found him busy with the study of natural things, his countenance cheerful, his mind serene, embracing all within its sphere. Our Harvey rather seems as though discovery were natural, a matter of ordinary business, though he may nevertheless have expended infinite labour and study on his works. And we have evidence of his singular candour in this, that he never hostilely attacks any previous writer, but ever courteously sets down and comments upon the opinions of each."

This account brings home to us the charm of

Harvey's personality. Beloved by his family and honoured by the College of Physicians, the old man went to his grave amidst the genuine grief of all who knew him. The publication of his essay on Development in 1651 was almost his last literary effort. His love for the College of Physicians remained unabated and he gave proof of it in a most practical manner, as he was the means of procuring a library and a repository for simples and rarities for the College, and before it was completed the College voted that a statue of Harvey should be placed in their hall. This was accordingly erected and represented Harvey in the cap and gown of his degree, and, though it perished in the Great Fire of London in 1666, it was not replaced when the College was rebuilt on or near its old site in the more recent building in Pall Mall.

Harvey died at Roehampton on June 3, 1657. Aubrey says that on the morning of his death, about 10 o'clock, he tried to speak and found that he had a "dead palsy" in his tongue, then he realised what was to become of him. He knew there were no hopes of his recovery.

It would appear that Harvey died of a cerebral hæmorrhage from vessels long injured by gout, and situated rather at the base or internal parts of the brain than in the frontal lobes. Most probably the left Sylvian artery gave way, leading at first to a slight extravasation of blood, which rapidly increased in quantity until it overwhelmed his brain.

Harvey's *liber aureus* is certainly his *Exercitatio anatomica de motu cordis et sanguinis in animalibus*. The work was issued from the press of William Fitzler, of Frankfort, in the year 1628. Harvey chose Frankfort as the place of publication for his book because the annual book fair held in the town enabled a knowledge of his work to be more rapidly spread than if it had been issued in England.

The treatise opens with a dedication to Charles I couched in fitting emblematical language, and signed—"Your Most August Majesty's Most Devoted Servant, William Harvey."

In the preface he excuses himself for the book, saying that he had already and repeatedly presented to them his new views of the movement and function of the heart in his anatomical lectures.

The anatomical treatise gives in seventeen short chapters a perfectly clear and connected account of the action of the heart and of the movement of the blood round the body in a circle. A movement which had been foreshadowed by some of the earlier anatomists and had been clearly indicated by Harvey himself as early as 1616. Harvey's proof fell short of complete demonstration for he had no means of showing how the smallest arteries are connected with the smallest veins. He worked, indeed, with a simple lens, but its magnifying power was too feeble to show him the arterioles and the venules, whilst the idea of an injection does not seem to have occurred to him. It was not

until after the invention of the compound microscope that Leeuwenhoek, in 1675, described the blood vessels, though they had already been seen by Malpighi.

The first chapter of the treatise is introductory. It is a review of the chief theories which had been held as to the uses of the heart and lungs. It had been maintained that the heart was the great centre for the production of heat. The blood was driven alternately to and from the heart, being sucked into it during the diastole, and driven from it during the systole. The use of the arteries was to fan and cool the blood, as the lungs fanned and cooled the heart, for the pulse was due to an active dilatation and contraction of the arteries. During their dilatation the arteries sucked in air, and during their contraction they discharged murky vapours through pores in the flesh and skin.

Harvey begins his chapter on the Movement of the Heart and Blood with the clear statement that the heart must be examined whilst it is alive, but he says—"I found the task so truly arduous and so full of difficulties that I was almost tempted to think with Fracastorius that the movement of the heart was only to be comprehended by God. For I could neither rightly perceive at first when the systole and when the diastole took place, nor when and where dilatation and contraction occurred, by reason of the rapidity of the movement, which in many animals is accomplished in the twinkling of an eye, coming and going like a flash of lightning."

After disproving the erroneous views of the heart's action, Harvey next proceeds to discuss the movements in the arteries as they are seen in the dissection of living animals. He shows that the pulsation of the arteries depends directly upon the contraction of the left ventricle and is due to it, whilst the contraction of the right ventricle propels its charge of blood into the pulmonary artery, which is distended simultaneously with the other arteries of the body. These facts enabled Harvey to disprove the current theory that the heart's systole corresponded with the contraction of the arteries, which then became filled with blood by a process of active dilatation, as bellows are filled with air.

The broad points in connection with the vascular system being thus settled, Harvey turned his attention more particularly to the mechanism of the heart's action. He shows that the two auricles move synchronously and that the two ventricles also contract at the same time. Hitherto it had been supposed that each cavity of the heart moved independently, so that every cardiac cycle consisted of four distinct movements. The minute accuracy of Harvey's observation is shown by his record of what is in reality a perfusion experiment. He says—"Experimenting with a pigeon upon one occasion after the heart had wholly ceased to pulsate and the auricles too had become motionless, I kept my finger wetted with saliva and warm for a short time upon the heart and noticed that under the

influence of this fomentation it recovered new strength and life, so that both ventricles and auricles pulsated, contracting and relaxing alternately, recalled as it were from death to life."

We now know that this was due to warmth, to the moisture, and to the alkalinity of Harvey's saliva, so that he performed crudely, and no doubt by accident, one of the most modern experiments to show that the heart, under suitable conditions, has the power of recovering from fatigue.

Harvey formulates in his fifth chapter the conclusions to which he had been led about the movement, action and use of the heart. His results appear to be absolutely correct by the light of our present knowledge, and they show how much can be done by a careful observer, even though he be unassisted by any instrument of precision. He further states—

"The great cause of doubt and error appears to me to have been the intimate connection between the heart and the lungs. When men saw both the pulmonary veins losing themselves in the lungs, of course it became a puzzle to them to know how or by what means the right ventricle should distribute the blood to the body or the left draw it from the venæ cavæ."

Furthermore he said—

"Had anatomists only been as conversant with the dissection of the lower animals as they were with that of the human body, the matters that have hitherto kept them in a perplexity of doubt would, in my opinion, have met them freed from every kind of difficulty."

After this plea for the employment of comparative anatomy to elucidate human anatomy, Harvey proceeds to deal in a logical manner with the various difficulties in following the course taken by the blood in passing from the vena cava to the arteries, or from the right to the left side of the heart.

It is a matter of historical knowledge that Harvey's views regarding the circulation of the blood were not accepted in toto. The exact teaching of his contemporaries in London is easily accessible. One of his distinguished colleagues at the College of Physicians was Alexander Reid (born in 1586), who learnt surgery in France, was admitted to the College of Physicians in 1624, and was appointed Lecturer on Anatomy at the Barber-Surgeons' Hall, December 28, 1628, in succession to Dr. Andrewes, Harvey's assistant. For some reason Harvey's doctrines did not recommend themselves to Reid, and his Manual therefore contains the following traditional account of the heart—

"As for the heart, the substance of it is compact and firm, and full of fibres of all sorts. The upper part is called Basis or Caput, the lower Conus Mucro or Apex Cordis. When the heart contracteth itself it is longer, and so the point is drawn from the head of it. But when it dilateth itself it becometh rounder, the conus being drawn to the basis. About the basis is the fat. It is covered with a skin which hardly can be separated. In moist and cowardly creatures, it is biggest. Of all parts of the body it is hottest, for it is the well spring

of life, and by arteries communicateth it to the rest of the body. The heart hath two motions, Diastole and Systole. In Diastole, or dilatation of the heart, the conus is drawn from the basis to draw blood by the cava to the right ventricle, and air by the arteria venosa (pulmonary vein) to the left ventricle. In Systole or contraction the conus is drawn to the basis."

However, the year 1628 may fairly be looked upon as the crowning year of Harvey's scientific life. It was that in which he published at Frankfort-on-the-Main his matured account of the circulation of the blood. After its publication he was sometimes heard to say that "he fel

mightily in his practice," for it was believed by the vulgar that he was crack-brained, and all the physicians were against him. But he lived to see his grand discovery universally accepted and inculcated as a canon in most of the medical schools of Europe, and he is said by Hobbs to have been "the only one who conquered envy in his lifetime and saw his new doctrine everywhere established."

The writer has quoted freely from "Masters of Medicine" by D'Arcy Power, F.S.A., F.R.C.S., Eng., written in 1897.

Association Notes

THE ANNUAL MEETING AN IMPRESSION

"Broad sweep of uplands close on either hand
Green upon green—a thicket here and there,
Hedging the red roads winding slowly down
By checkered fields and meadows lush with grass
To where in misty blue above the town
Soft lights and colours tremble as they pass."

This thumb-nail sketch by an Island writer fairly describes a visitor's first impression of Prince Edward Island, and, travel over the Province as he may, he is never out of sight of just such a picture, and June makes cleaner and fresher, if that were possible, the face of nature here outlined. In the fifty-nine years of the history of the Canadian Medical Association this is the first in which a general meeting has been held in the smallest Province of all—itsself the cradle of Confederation.

Many feared that a meeting so large as this would swamp a meeting place so small, but industry and preparation on the part of the local profession and of the executive of the Canadian Medical Association overcame all obstacles and brought to pass a meeting which will stand unique in the annals of the Association.

Whoever received the inspiration which caused the chartering of a steamship which would sail from Montreal and act as a floating hotel for its passengers during their stay in Charlottetown was the one who assured the success of the meeting, for, aside from easing the strain upon the local accommodation, the voyage down the river and gulf made and cemented friendships among far-removed members of the Association, which generated a homogeneous nucleus for the whole gathering and became the guarantee of a successful meeting.

Many cities of Canada have greeted the Association with open-handed hospitality, but seldom in the memory of the most blasé has a welcome to the body been so spontaneous and whole-hearted. It can readily be seen that all the medical men in a city of 12,000, or in a Province of 88,000 people, if they worked all the time, could not alone take care of a registration of 560 delegates, but they had enlisted the enthusiastic co-operation of all the citizens, and the members

and their friends had thus actually bestowed upon them the Freedom of the Province. It was indeed difficult to keep pace with the entertainment which was provided.

Very wisely, it would appear in this instance, the Executive arranged that the medical program would be carried out in general meetings only. A roll-call would have discovered but few absentees from the sessions, and the papers as a rule were chosen with a view to their general interest, and maintained a high average of quality.

It is impossible to eat one's cake and have it too, and it would not be fair to expect from papers planned for their general adaptability any records of detailed interest to men working in special fields, but in succeeding meetings to be held in larger centres the Committee would be well-advised to consider an appeal to the interest in more advanced subjects, while by no means ignoring the review of general questions. Leaving aside, however, all questions of strictly medical interest, the bringing together of more than five hundred intelligent Canadians for a common purpose, and showing to them a part of their national heritage which they had not seen before, is in itself a matter of no small importance for themselves, for each other, and for the peace and unity of Canada.

A. H. GORDON

The following letter, which is self-explanatory, has been sent to the *Journal* for publication.

MY DEAR DR. ROUTLEY

Many thanks for your kind letter telling me of the honour the Association has done me by electing me a senior honorary member of the Association. As a past President and one of its early members I have always taken a great interest in the Canadian Medical Association and am glad to hear how prosperous it is.

Hoping you will let the members know how proud I am of the honour conferred, I am,

Sincerely yours,

F. J. SHEPHERD

Montreal, July 11, 1928

Provincial Association Notes

THE BRITISH COLUMBIA MEDICAL ASSOCIATION

The annual meeting of the British Columbia Medical Association was held at Victoria on June 11th and 12th. The Empress Hotel was the headquarters for the meeting. Owing to the strenuous efforts of the Victoria Medical Society, and especially the organizing committee under the chairmanship of Dr. M. W. Thomas, this year's meeting was a great success, preparations having been made for entertainment as well as the presentation of scientific papers and transaction of the business of the Association.

Several members brought their wives to Victoria and these were delightfully entertained. A golf tournament was organized, and Drs. Lachlan MacMillan and C. H. Vioman of Vancouver, were the successful players, though the latter was considerably impoverished in the matter of balls owing to the somewhat unique hazards encountered on the Oak Bay Golf Course.

Three of the members of the post-graduate tour, Drs. F. A. C. Scrimgeour, V.C., F. H. MacKay, and Andrew Hunter gave lectures on both of the days during which the meeting was held. These were fully up to the standard that they set in the meeting of the Vancouver Summer School.

On Tuesday morning a meeting of the Executive was held with twelve members present. Dr. W. S. Turnbull, President of the Vancouver Medical Association, was also present at the meeting and spoke on the suggested closer co-operation between the Vancouver and the British Columbia Medical Associations. This was one of the most important matters taken up at the meeting, and it was strongly felt by the Executive that the time had arrived for a more business-like arrangement, from the point of view of both Associations, to reduce expenditures and to increase the efficiency of the services given to the profession. A very full discussion took place and every member of the Executive supported the idea that no stone should be left unturned to bring the two Associations closer together, even if this meant some sacrifice on both sides. The question of details it was felt had to be left for future arrangement, but it was decided to recommend to the full meeting that the British Columbia Medical Association endorse the principle of a closer co-operation and this suggestion was whole-heartedly accepted by the later meeting of the full Association. At the meeting of the Association held in the evening reports were given by the chairmen of the various committees. The Industrial Service Committee presented a remarkably full and com-

plete report, and showed a tremendous amount of work done by the business office of the British Columbia Medical Association. Contracts, Indian Department work, grants to medical men, payment of accounts, and the supplying of medical men both as locum tenentes and as permanent residents in various parts of the province, were referred to, and it could be seen in many instances how essential it is to the profession in British Columbia that there should be a strong central office keeping close watch on the hundred and one difficult problems that come up from day to day. Work has been done in regard to the Provincial Income Tax, and on the question of Coroners' fees, though this matter has not yet been satisfactorily settled. The question of Marine Hospital and Medical Services, which has been taken up by the Canadian Medical Association, was referred to this Association for a report and Dr. C. W. Prowd's report on the matter has been published among the reports of the Federal Organization.

In the matter of the Indian Department an additional \$50,000 per year has been given by the Dominion Government, to be applied to medical services in this province, and in this matter our Executive Secretary has done a tremendous amount of work of great value to the Indian Commissioner at Victoria, Mr. Ditchburn. The Auditor's report showed a decrease in expenditures over last year of \$623, a slight increase in membership, and a balance on the credit side, which is satisfactory in that it is neither too big nor too small.

The question of Health Insurance was taken up at this meeting and it was decided to appoint a committee to go fully into the matter immediately and keep the members in touch with the situation as it develops.

Eleven new members, as under, were approved and accepted: Edwin Johnston Curtis, Arthur George Elvin, William Elliott Harrison, John Allan Iceland, Thomas Campbell Melue, F. P. McNamee, Arthur Percival Proctor, Walter Scott Turnbull, Andrew Russell Wilson, Charles Arthur Watson, Lionel B. Winch.

The following officers were unanimously elected for the ensuing year: President, Dr. Wallace Wilson, Vancouver; President-Elect, Dr. W. A. Clarke, New Westminster; Vice-President, Dr. Theo. H. Lennie, Vancouver; Secretary-Treasurer, Dr. G. Lyall Hodgins, Vancouver; three members of the Executive at large, Dr. J. McKee, Courtenay, Dr. A. L. Jones, Revelstoke, Dr. R. McCaffrey, Chilliwack. The retiring President, Dr. H. E. Ridewood, spoke on the work of the association and thanked the members of the executive for the splendid work they had done.

THE ONTARIO NEURO-PSYCHIATRIC ASSOCIATION

The Spring Meeting of the Ontario Neuro-Psychiatric Association was held at the Westminster Psychopathic Hospital, London, Ontario, on June 11th

The meeting was called to order at 3 p.m. by the President, Dr R. G. Armour. Dr McLean, Acting Superintendent of Westminster Psychopathic Hospital, gave an address of welcome to the members of the Association. The President then gave an interesting address on the work that is being carried on in the Ontario Hospitals.

Dr Armour dealt with the progressive spirit that is prevalent in the hospitals, some of which can be appreciated by the program of the day. He also made a plea for larger medical staffs in the Ontario hospitals, which might allow of more investigation into physical problems as well as psychiatric phenomena.

Dr R. Fletcher, Toronto, read a paper, "Report of work done at the Ontario Hospital, Toronto, with special reference to Sulfoxyl Salvarsan and non-specific protein."

Dr Fletcher had been using large doses of typhoid vaccine as a non-specific protein, and had had some encouraging results in cases where the arsenical preparations could not be used. The percentages of improvements and cures in connection with general paresis is gradually climbing, some statistics passing from the thirties into forty-odd per cent. There could be no doubt that the old feeling that nothing can be done for any parietic is passing away.

Discussion was opened by Dr Crawford, Psychopathic Hospital, Toronto, and continued by Dr Fisher, London.

Dr C. H. Pratt, Ontario Hospital, Woodstock, then read a paper, "The treatment of epilepsy," and showed some very interesting lantern slides illustrating the use of luminal and belladonna in its treatment.

Dr Pratt's work on epilepsy is outstanding. His report contained records of exact numbers of convulsive attacks in institutional cases over periods of two to three years, and his methods were bringing under control cases that resist the older methods of treatment. By using large doses of caffeine and belladonna, the latter in doses of twenty or more minims of the tincture three times a day, he was able to increase the dose of luminal to as much as nine grains a day without any untoward effects. It was interesting to see his patients a half to one hour after one of these large doses of belladonna with small and active pupils and no dryness of the mouth.

Discussion was opened by Dr McCausland, Kingston, and continued by Drs Nichol, London, Cumberland, Woodstock, Cathcart, Ottawa, Tennant, London, and Armour, Toronto.

The meeting adjourned at 5.40, and refreshments were served in the Nurses' Home, where the members were entertained by Dr and Mrs McLean and the Staff of the Westminster Hospital.

The evening session was called to order at 7.15 p.m. by the President.

Dr Lynch, Brockville, read a paper, "Intensive use of bromides in the treatment of functional psychosis."

Dr Lynch is using as much as three hundred grains of bromides a day. He finds the sodium salt the least irritating. An example of how he administers the drug would be, one hundred and fifty grains at eight o'clock in the morning, and seventy-five grains at four o'clock in the afternoon. Sometimes this is given merely dissolved in a cup of tea. Toxic effects were observed in the first few cases that were allowed to remain in bed, but by keeping the patient up and about, particularly after the larger dose, this effect was avoided. Less trouble was experienced from rashes with these larger doses than with the more conservative amounts in common use. Indications as to what was being obtained in many different types of patients, manic-depressives, in dementia præcox, and in involutional psychoses, were the correction or relinquishing of delusions, calming of agitation, lessened bed-wetting and other soiling, and a generally more peaceful ward.

The discussion was opened by Dr G. C. Kidd, Kingston, and continued by Drs Robinson and Chalk of London, McLean, London, Pratt, Woodstock, Towers, London, Cumberland, Woodstock, Cathcart, Ottawa, and McCausland, Kingston.

A Round Table Conference was called to order at 8.25 p.m. and many matters of importance were discussed. The meeting adjourned at 9.30 p.m.

From time to time a journal of the proceedings of this association is published by the Department of the Provincial Secretary and distributed to the members of the profession throughout the province. It will always be found worth while reading. Members of the profession generally will always be welcome at the meetings of this association in the different places in which it meets, its aim being to form a link between the general practitioner and the psychiatrist.

"Truth is an immortal and eternal thing. It bestows, not a beauty which time will wither, nor a boldness of which the sentence of a judge can deprive

us, but the knowledge of what is just and lawful, distinguishing from them, and confuting what is unjust."

—*Epictetus*

Reports of Societies

WESTERN NOVA SCOTIA MEDICAL SOCIETY

The annual meeting of the Western Counties Branch of the Medical Society of Nova Scotia was held at Yarmouth on the twenty-ninth of May. Dr. Elliott P. Joslin, of Boston, was present, and contributed an important address. There was a very large attendance.

In order to facilitate matters, the first day's session was devoted entirely to the reading and discussion of papers, and all business matters were left over to an adjourned meeting held on June eleventh.

The first paper was by Dr. A. R. Campbell, of Yarmouth, on "Surgical Diseases of the Testicle." Dr. Campbell outlined the signs and symptoms of the various surgical conditions of the testicle together with the differential diagnosis. He explained that perhaps no other organ excepting the breast suffered from errors in diagnosis more than did the testicle. He sketched the histological formation and the early pathological conditions which are met with. He explained the development of the testicle and outlined Stinach and Voronoff's treatments for rejuvenation. Dr. Campbell explained the treatment for tuberculous epididymitis and the differences between this and other lesions involving the epididymus and testis proper.

The second paper was by Dr. Elliott P. Joslin, of the New England Deaconess' Hospital, Boston, and was entitled "The Care and Treatment of Diabetics." Dr. Joslin outlined the procedure which he followed at the Deaconess' Hospital, stressing particularly the necessity of attention to minute details in diabetic patients and watching for early complications and anticipating them. This he emphasized particularly in the care of the lower extremities. Dr. Joslin explained how he treated diabetic gangrene, and

laid special stress on the use of insulin in all surgical conditions. Diabetes in children was particularly considered. Before insulin was discovered this was a hopeless condition, but since its introduction it has changed the picture and gives new life to children so afflicted. He further showed how he administered insulin, using different places for each injection. The difference between the coma of diabetes and hypoglycæmia was explained.

At the adjourned session, Dr. Farrish was again in the chair. It was decided that the Society, having already agreed that the annual meeting of the Medical Society of Nova Scotia should be held at Charlottetown, were now willing to agree to any re-arrangement that met with the endorsement of the other branch societies.

It was moved and seconded that this society go on record as heartily endorsing the program put forward by the Nova Scotia Tuberculosis Commission.

The report of the Secretary-Treasurer was read and adopted.

The election of the officers for the coming year resulted as follows: President, Dr. J. E. LeBlanc, West Pubnico; Vice-Presidents, Dr. L. M. Morton, for Yarmouth Co., Dr. P. L. Belliveau, for Digby Co., Dr. H. H. Banks, for Shelburne Co.; Secretary-Treasurer, Dr. Thomas A. Lebbetter, Yarmouth; representatives on the Nova Scotia Medical Society Executive, Dr. G. W. T. Farrish, Dr. W. C. O'Brien.

It was moved and seconded that the Society send a letter of condolence to the family of the late Dr. A. J. Fuller.

Dr. Lebbetter was appointed to represent the Society on the "Osler Memorial Fund" Committee.

T. A. LEBBETTER,
Secretary-Treasurer

The Physician—There are men and classes of men who stand above the common herd, the soldier, the sailor, the shepherd not infrequently, the artist rarely, the physician almost as a rule. He is the flower of our civilization, and when the stage of man is done and only to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period and most nobly exhibited virtues of the race. Generosity he has, such as is possible to those that practice an art, never to those who drive a trade. Discretion, tested by a hundred secrets, tact tried in a thousand embarrassments and, what are more important, Herculean cheerfulness and courage.—Robert Louis Stevenson

"There are two methods of obtaining knowledge—by argument and by experiment, argument makes conclusions and forces us to agree to them, but it does not make us feel certain or so remove suspicion that the mind rests in assurance of truth, unless this be also found by experience."—Roger Bacon, *Opus Majus*, Pars VI, cap. I

"Thou mayest always speed, if thou wilt but make choice of the right way, if in the course both of thine opinions and actions, thou wilt observe a true method."—Marcus Aurelius

Correspondence

The Edinburgh Letter

(From our own correspondent)

An interesting side light on the expedients of the Voluntary Hospital System is obtained once a year on "Infirmity Day." On that particular occasion, the activities of a week's endeavour to raise money in support of the Infirmary come to a climax. Battalions of collectors in every variety of fancy costume are let loose upon the city. These parade the streets, encamp upon doorsteps, enter shops, hotels, street cars, and restaurants, and even invade the inner sanctuaries of clubs. The ordinary citizen on his way to the office may expect to have a fresh money-box rattled under his nose at every few yards. As often as he appears in the street, so often may he expect to be importuned, solicited and finally effectively fleeced. The man in the street may be permitted to speculate on the practicability of an arrangement that allows highwaymen to thrust pistols in his face, permits Red Indians to threaten him with tomahawks, and sanctions Samoan natives brandishing menacing clubs over his head. It may be that the voluntary hospital system is on its last legs, if so there was no sign of its being doomed at this year's Infirmary day. The collectors by a series of hold-ups gathered more money than ever before. The culminating point was reached when a pageant about two miles long paraded the principal streets. This consisted of numerous pipe and brass bands, a series of tableaux on motor lorries, and the appearance of representatives of every branch of the community: fishermen, firemen, coalminers, shepherds in procession. The proceedings terminated in a student carnival in the Waverley Market, which was opened by Sir John Gilmour, Lord Rector of Edinburgh University, and Principal Sir Alfred Ewing.

In the end of May, Sir W. Leslie Mackenzie retired from his post as medical member of the Scottish Board of Health. Sir Leslie is proceeding to Kentucky. He has accepted an invitation to inaugurate a new hospital service which has been formed in the mountainous districts of the Alleghany region. This medical scheme has been modelled on a plan, similar to the services in the Highlands and Islands of Scotland, for the conception of which Sir Leslie was so largely responsible. Sir Leslie is to be accompanied by Lady Mackenzie, who has always taken a lively interest in Public Health matters in Scotland. The choice of Sir Leslie to inaugurate this scheme is a tribute to his success as an administrator, and would appear to be an acknowledgement of the success of the Highlands and Islands Service.

The University Court, on the recommendation of the Senatus, has approved a revised scheme of the curriculum of courses for the University Diploma in Tropical Medicine and Hygiene. This new course has been devised to meet the requirements particularly of officers of the Colonial Medical Services. The University of Edinburgh has been specially recognized by H. M. Colonial Office, as an institution in which these officers may pursue the study of tropical medicine, either on first appointment or on special leave of absence during their service.

The Annual Golf Match between the Royal Colleges of Physicians and Surgeons was played on May 21st over New Luffness Course, and resulted in a win for the Surgeons by 18 matches to 1. Certainly the Surgeons have taken summary vengeance for the Physicians' victory in the curling match last March.

The Harveyan Festival was held in the Royal College of Physicians on June 1st. This event has taken place annually since 1787, when the club was founded by Dr. Andrew Duncan (senior) to commemorate William Harvey. Dr. Robert Thun, President of the Edinburgh Harveyan Society, occupied the Chair, and treated a large gathering to an interesting address upon Archibald Pitcairn in relationship to Harvey. This medical scientist, in addition to being a poet and man of letters, was an ardent Jacobite politician. Largely as a result of his work in connection with Harvey's discoveries, Pitcairn was appointed Professor of Medicine at Leyden. Returning to his native country he must be regarded as the real founder of the Edinburgh Medical School. After an eloquent and arresting address the society and its guests dined in the Hall of the College.

Dr. F. A. E. Crew, M.D., D.Sc., Ph.D., has been appointed by the Court of the University of Edinburgh to be Professor of Animal Genetics and Director of the University Department of Research in Animal Breeding. The Chair is to be known as the Buchanan Chair of Animal Genetics. It was founded by a donation from Lord Woolavington, supplemented by a grant from the International Education Board, New York. Professor Crew, the first occupant of the Chair, is a graduate of Edinburgh University. In 1920 he was appointed Director of the newly created Animal Breeding Research Department. In 1927 Dr. Crew was William Withering Lecturer at the University of Birmingham, and in 1928 Milroy Lecturer at the Royal College of Physicians, London. Several books dealing with his subject have been published over his name. These include "Animal Genetics," "Genetics of

Sexuality in Animals," "Organic Inheritance in Man," and "Heredity", also he has written many scientific papers. In addition to his purely scientific pursuits, Professor Crew is Commanding Officer of the Medical Unit of the University O T C.

Edinburgh has sustained a sad loss through the death of Sir James Hodsdon, K B E, F R C S, on May 28th. For many years he took a prominent part in the medical life of the city. Born in Bermuda in 1858, he graduated M D at Queen's University, Belfast. In 1883 he obtained the Fellowship of the Royal College of Surgeons, and ultimately became President of the College during the stirring years of 1914 to 1917. He has represented his College since 1906 on the General Medical Council. During the War he did valuable work on the Staff of the 2nd Scottish General Hospital, the Emergency Committee, and on various Appeal and Pension Boards. As a hospital surgeon, a teacher and administrator, his work was of merit and importance. His death comes as a great personal sorrow to those with whom he was associated in these and other capacities.

GEORGE GIBSON

THE PRODUCTION OF A NEW TUMOUR

To the Editor

I have read with much interest the paper of Dr. Briebner in your issue of April, 1928, p. 397.

There are, however, some erroneous statements made in regard to the literature, to which it is necessary I should call attention.

The statement is made that "Warburg (*Biochem Zeit.*, 1923, cxlin, 317) had shown that tumour and placenta are comparable metabolically, in that they both have a high aerobic and anaerobic glycolytic activity."

This is wrong. The paper, to which reference is made, contains neither the word "placenta" nor any synonymous term. Negelein, working in Warburg's laboratory later, examined the maternal mucosa and the fused amnion and chorion as we believe, but not the invading chorionic epithelium, and found no such metabolic result as that which Dr. Briebner ascribes to Warburg. Indeed, Warburg has stated that placenta (presumably meaning chorionic epithelium) does not behave like malignant tissue.

As a matter of fact, Murphy and Hawkins (*Journ Gen Physiol*, 1925, viii, 115), working with Warburg's method, were the first to show that the "placenta" behaves like malignant tissue in respect of aerobic glycolysis, but doubtless they were acquainted with our work and views, previously published, regarding the malignant nature of the chorionic epithelium.

We ourselves (*Brit M J*, 1926, i, 687, *Idem*,

1928, i, 126, and *J Obst & Gynaec Brit Emp*, 1928, xxxv, 233), have demonstrated that the chorionic epithelium possesses the power of aerobic glycolysis, and we have fully discussed the whole subject. Loeser, also, (*Centralb f Gynaek*, 1926, l, 1819), has published some in conclusive evidence on the same subject.

There is no doubt, however, that we have been the first definitely to demonstrate from every point of view that the chorionic epithelium is a malignant tissue, and to base our work on malignant disease on our findings in this respect.

I wonder whether Dr. Briebner can obtain tumours without using chick embryo as well as placental tissue, for our own attempts to produce malignant tumours from chorionic transplants have not so far given positive results.

W. BLAIR BELL

Liverpool, England, June 14, 1928

ON THE DIAGNOSIS OF HYPERTENSION

To the Editor

As a diagnosis of hypertension seems to be rather prevalent these days, it seems to me there should be some unanimity among medical men as to what should be told patients about their blood pressure.

Personally I find elderly people, who have consulted a doctor while away on a visit, or have gone to a different climate for the winter, return with a definite figure of their blood pressure reading, always the systolic. They come regularly afterwards to have their blood pressure taken, and demand to know the figure, which, unfortunately for their own peace of mind is usually not much reduced. They are aware that high blood pressure may be a forerunner of apoplexy, and they spend the remaining years of their life in dread of an impending calamity.

This worry may do as much towards keeping the blood pressure high as our treatment in getting it reduced. Before the days of the sphygmomanometer old folks spent their last days happy and content, unaware that they were on the brink of a precipice. Now they know their danger, and even if we prolong their life a year or two by proper treatment, they know that we are not getting them far away from the edge of the precipice.

Instead of diagnosing high blood pressure as a disease and telling patients how high it is, if we went farther, and tried to find the cause of the hypertension, treated our patients for the cause, kept track of the blood pressure, systolic and diastolic, as an aid in prognosis and treatment, we would be doing our patients a kindness. We would also relieve ourselves of the necessity of explaining to them that a sudden drop in blood pressure would be a greater calamity than if it remained stationary.

My purpose in writing is to try and get some

helpful discussion on this question. You might bring it before the readers of the *Journal* in some way so that a fairly unanimous opinion may be reached as to whether or not it is better to tell patients how high their blood pressure is.

Yours sincerely,

W A CHESTNUT

Moosomin, Sask

June 25, 1928

P.S.—If you think it is better to tell them I am willing to fall in line.

W A C

FOUR CENTURIES OF MEDICAL HISTORY IN CANADA

This letter, which is self-explanatory, has been sent by the writer to the *Journal* for publication, with the concurrence of Dr Heagerty. Dr Heagerty's statement on the matter appears also (Ed)

Dr J J Heagerty,

Department of Health, Canada,

Ottawa, Ontario

Dear Dr Heagerty

When the announcement of your book, "Four Centuries of Medical History in Canada," arrived I immediately sent for a copy and have read it with great interest. At the request of the editor I have reviewed the work for *The Canadian Nurse*, the official organ of the Canadian Nurses Association. May I congratulate you very heartily on the historical value of your book. The story of the founding of the first hospitals in Canada deserves to be published to the world and in your volumes that story has been well told.

When one realizes the immense amount of time and labour expended by you in the preparation of this work, the sifting over multitudinous documents in the Dominion Archives and elsewhere it seems almost ungracious to interject a word or two of adverse criticism. Coming from the position you occupy, however, your book has an authority which might be lacking had it been written only by one of the rank and file of the profession. The criticism is this that, no doubt inadvertently, there has been insufficient recognition of the achievements of the west and when the merits of the east have been lauded as they are that thereby an injustice has been done to Western Canada and its institutions.

May I state my points. Part 5 of the book deals with medical schools. On page 56, volume II, occur these words "In 1903 the University of Saskatchewan offered a partial course in medicine, and in 1906 the University of Alberta did likewise. In the year 1910 there were eight medical schools in Canada. These were studied by the Carnegie Foundation for the Advancement of Teaching, a report of the study being published on April 16th of that year. Each school was visited and the findings

approved by two or more independent observers. While some of the schools were unequivocally condemned for lack of equipment and hospital teaching facilities, others, notably Toronto and McGill, received well merited praise." Then followed extracts from the report dealing with these two schools. The next paragraph continuing, "Since that report was made both Toronto and McGill have made further progress which places them in the ranks of the foremost medical schools of the continent. The course in Canadian universities is now a six-year one."

While no one will deny that Toronto and McGill rank deservedly with the leading medical schools of this continent, it is only in accordance with the facts to point out that since 1923 the Medical Faculties of both Manitoba and Alberta Universities have received Class A, the highest, rating. The Education Number for the *Journal of the American Medical Association*, August 16, 1924, gives the rating of all medical schools in the United States and Canada. In the list of Canadian schools Alberta and Manitoba are shown as Class A along with Toronto and McGill. In 1923 the University of Alberta offered a complete medical course and already two or three classes have been graduated from that institution.

To my mind it does seem unfair to Manitoba and Alberta to make reference in a work published in 1928 only to the 1910 report of the Carnegie Foundation and not to quote from subsequent reports.

Part 6 of your work deals with Hospitalization. On page 192, volume II, under the heading Toronto General Hospital occur these words "The hospital is proud of the record and reputation of its Nurses Training School, which in 1926 graduated 84 nurses, being the largest class ever graduated from a Canadian hospital." The class of nurses graduating in 1925 from the Training School of the Winnipeg General Hospital numbered 95, and the class graduating in 1928 numbered 96.

As evidence of the achievements in medical history in Western Canada may I point out the following:

A psychopathic hospital was built on the grounds of the Winnipeg General Hospital in 1919, the first to be established in Canada.

In 1910 the first Social Service Department in connection with a Canadian hospital was inaugurated at the Winnipeg General Hospital.

In January, 1921, a prenatal clinic was organized at the Winnipeg General Hospital and in April, 1927, a post-natal clinic.

Manitoba led the way among the other provinces in the establishment of District Health Nurses by the late Hon. Dr J W Armstrong, vide *Canadian Medical Association Journal*, vol XVII, No 4, April, 1928, p 475.

May I also point out that in vol II page 285, the name of the superintendent of Brandon

Mental Hospital should be Dr C A Baragat, and not Barraghei as printed

In closing may I add that the foregoing criticism is not made in any spirit of sectionalism. Osler warned us against Chauvinism and that is a warning which Canada with its immense distances and sparse population particularly needs to heed. It is only because I have a great admiration for the services you have rendered to the cause of medical history in Canada that I wish in all kindness to point out the seeming inaccuracies or lack of proportion in your book, which may be corrected in a later edition.

Will you kindly accept the gratitude of a Canadian physician

Yours sincerely,

ROSS MITCHELL

To the Editor

I wish to thank Dr Mitchell for his letter of appreciation of "Four Centuries of Medical History in Canada" and to acknowledge my indebtedness to him for pointing out certain omissions and apparent lack of proportion in those chapters treating of the West and the Province of Manitoba in particular.

The lack of proportion to which Dr Mitchell makes reference is more apparent than real. It is self-evident that the records of institutions which have been in existence for a period of three hundred years or more, such as those of the East will of necessity contain more historical material than institutions that have come into existence within the past few years, such as those of the West. Eastern institutions, on account of their age offer more in the way of historical material than those of the West, and to them, therefore, more space has been afforded.

I am sure that the readers of "Four Centuries of Medical History in Canada" will appreciate the impossibility of doing full justice to each and every medical institution in Canada, of

which there are hundreds, within the scope of two short volumes. When, in addition, one considers the tremendous amount of ground that was covered, the difficulty of eliciting every fact in connection with such institutions will be only too evident.

It is to be regretted that in the chapter on medical schools the impression was created that a comparison was made of the relative merits of existing schools. Such was not my intention. In writing so fully of McGill and Toronto, I wished only to give a word of well-merited praise to two of the oldest and foremost schools of Canada—two schools that compare favourably with the best anywhere.

A reference to the chapter on the University of Manitoba, which concludes with the following words —

"The University of Manitoba offers facilities for undergraduate medical training equal in all essentials to that of any Canadian school, and promises, as in the past, a steady advance in modern educational methods and continually widening opportunities for medical research,"

shows clearly that I was fully appreciative of the high professional standing of that school. Several visits to the western schools have convinced me of the great strides that are being made by those young institutions, and I fully realize that in respect of medical education the East will have to look to its laurels. If I have dwelt at greater length upon the older medical schools and institutions, it is because they offered more fertile ground for research, and to the student of history the older institutions make a more insistent appeal.

I am nevertheless fully seized of the importance of Dr Mitchell's kindly and frank letter, which was so evidently written in a spirit of helpfulness, and I am grateful to him for the valuable suggestions he has made.

Yours very truly,

J J HEAGERTY

Ottawa, July 13, 1928

"The physician should be of a tender disposition, of wise and gentle nature, and more especially an acute observer, capable of benefiting every one by accurate diagnosis, that is to say, by rapid deduction of the unknown from the known. And no physician can be of tender disposition if he fails to recognize the nobility of man, nor of philosophical nature unless he be strengthened by God's guidance, and he who is not an accurate observer will not arrive at a correct understanding of the cause of any ailment."—Nizami Arudi, Court Poet of Samarcand

"We ought to choose both a physician and a friend, not the most agreeable, but the most useful."—

Epictetus

"A wise man will hear, and will increase learning, and a man of understanding shall attain unto wise counsels."—*Proverbs of Solomon*, I, 5

"It is the glory of God to conceal a thing, but the honour of kings is to search out a matter."—*Proverbs of Solomon*, XXV, 2

Topics of Current Interest

POST-OPERATIVE TETANUS

The following abstract from the *British Medical Journal* (1928, 1, 937,) is a digest of a report on post-operative tetanus by Dr T J Mackie, Professor of Bacteriology, University of Edinburgh. The importance of the subject cannot be over-emphasized.

"The occurrence of a series of cases of post-operative tetanus in an institution led the Scottish Board of Health to request Dr T J Mackie, Irvine Professor of Bacteriology in the University of Edinburgh, to investigate the matter. Since this infection has in the past been associated with catgut, Professor Mackie was asked at the same time to report also upon the effectiveness of the means employed for sterilization of catgut in its manufacture, storage, and use in hospital, the dangers attendant on its use in surgery, and the best available means for effective sterilization during manufacture, storage, and use in hospital. The report of this inquiry has now been published by the Stationery Office, at the very low price of 1s. Professor Mackie, who was assisted in the inquiry by Dr G S M'Lachlan, lecturer in bacteriology at Edinburgh University, believes that the investigation has not only elicited data of the utmost significance in regard to the whole problem of post-operative tetanus, but has also led to an extended study of preventive methods which deserves the most careful attention. The Scottish Board of Health expresses its full agreement with Professor Mackie's assessment of the importance of the facts now published.

INCIDENCE AND ETIOLOGY

The report opens with references to the literature showing that post-operative tetanus has been commonly attributed to catgut, though cases have occurred in which this material was not employed, and auto-infection was incriminated. The valuable suggestion is proffered that information should be collected systematically regarding the incidence of post-operative tetanus in all the general hospitals in Great Britain, since at present it is probable that many cases are not published. It is well known that *B. tetani* occurs as a commensal organism in the alimentary canal of various herbivorous animals, including the sheep, from the intestines of which surgical catgut is prepared. Other anaerobic sporing bacilli capable of producing serious wound infections are also found in the intestine, and the conditions prevailing in abattoirs from which the raw material for making catgut is obtained render contamination very easy. Subsequent sterilization of the catgut is a particularly difficult matter owing to the resistant powers of the tetanus spores. Post-operative infections by other sporing bacilli have also been reported, and

this emphasizes the difficulty of adequate sterilization of the catgut. During the period in which the cases of post-operative tetanus occurred at the institution in question, the surgical catgut employed was supplied almost entirely from one source, mostly in the form of "dry strings," which had already undergone some measure of sterilization but were subjected to further bactericidal treatment before being used in operations. During the investigation this supply of catgut was stopped.

CLINICAL DETAILS

Of the eleven cases of post-operative infection in the institution considered in the report one had occurred so long ago as 1923, in no instance was it possible to trace any connection between the catgut used for the various patients, and the operations in the more recent cases were separated by intervals of twelve, nineteen, nine, and seventeen days. The highly significant fact was elicited that in gynaecological repair operations a considerable amount of catgut remained embedded in the tissues, it was estimated by one surgeon that approximately 69 inches might be so left after a repair operation for complete prolapse of the uterus. Moreover, in such operations it is a common practice to employ the thicker gauges of gut. Though *B. tetani* was not always demonstrated, there was little doubt about the diagnosis in any of the patients in view of the clinical and pathological data.

In the whole series there were nine cases of definite tetanus, one of gas gangrene, and one of a sporing anaerobe infection with muscular spasms. Ten different surgeons were concerned, and six operating theatres. All the patients died except one, in whom tetanus supervened after a repair operation for a retroverted uterus and a deficient perineum. The incubation period in this case was fourteen days, as contrasted with incubation periods of seven to twelve days in the fatal cases. The time of death after the onset of tetanus ranged from a few hours to five days. *B. tetani* was demonstrated in two cases, tetanus-like organisms were found in two, and other sporing organisms in two cases. No organisms were isolated in one case, and in two others no bacteriological examination was performed. Negative bacteriological findings are admittedly of little significance in the diagnosis of tetanus cases. Five of the nine cases occurred after operations in one theatre which was on the ground floor and close to a main corridor. Constructional work was proceeding in its neighbourhood, but no further evidence was obtained indicating that these local conditions were concerned in the infection. The possibility of auto-infection was carefully considered, but this

explanation had to be dismissed in the absence of data

CONTAMINATED CATGUT AND TETANUS

Professor Mackie mentions that the preparation of the catgut included (1) twelve hours' immersion in a watery solution of mercury biiiodide, (2) heating at 160° C for one hour in oil, (3) heating in anhydrous spirit in a Jellett's sterilizer in boiling water for one and a half hours, (4) storage in an antiseptic fluid containing a mixture of mercury biiiodide and other antiseptics. The technique of the last three procedures was carefully reviewed, and no evidence was obtained of any carelessness or inexactitude. The dry catgut strings were tested, and were found to contain sporing anaerobic bacilli of the group to which *B. tetani* belongs, these (*B. tetani* and *B. mesentericus*) were used for testing purposes, and it quickly became obvious that exposure for twelve hours to the watery solution of mercury biiiodide could have but little effect. A certain proportion of the spores of *B. mesentericus* survived heating in oil at 160°, and the margin of the destruction of *B. tetani* was very narrow. The ineffectiveness in this respect of heating in a Jellett's sterilizer was completely demonstrated, and spores remained viable finally after storage in the mixed antiseptic solution. In only one procedure was *B. tetani* destroyed. Intermittent sterilization in heated oil was tried but was found to ruin the catgut, as did also streaming steam sterilization and exposure in an autoclave to superheated steam. The efficiency of very many chemical bactericides was tested, hydrogen peroxide and iodine water proved to be the best, but the action of some reputed bactericides was found to be surprisingly feeble. It was concluded finally that catgut "ribbons" could best be sterilized by immersion in hydrogen peroxide (10 vols) for twelve hours, the catgut strings spun from these ribbons being further exposed for fourteen days in iodine water. These procedures, which do not damage the catgut, can be employed in factories, it is suggested that, subsequently, the strands should be passed through two changes of spirit to remove the iodine, and be stored in 50-75 per cent alcohol containing 0.1-0.2 per cent iodine. It is added that these processes should be controlled in operation by bacteriological examinations.

ENCEPHALITIS LETHARGICA

The insidious nature of encephalitis lethargica, the difficulty of diagnosis, the high death-rate of the disease, and the low proportion of cures effected are points emphasized in a report on this malady issued recently by the Ministry of Health, the work of Mr. Allan C. Parsons, M.R.C.S.

Among the points emphasized are

"The disease is still a comparative novelty and its onset is often so insidious that it attracts no attention even from the patient himself

"Since 1919 no fewer than 14,321 cases have

been notified, and 6,477 deaths are registered as having been due to this cause

"The proportion of those who recover from the acute attack sufficiently to pursue their usual occupation with little incapacity is only about 25 per cent."

Records show that a fatal ending to the disease is more frequent among patients who are attacked at the two extremes of life

"There is probably no infectious or contagious disease in the country which produces so much consequent ill-health and disablement," the report adds

"If the total number of those who are annually maimed by encephalitis lethargica is an insignificant proportion of the general population, the individual victims of this disease are often conspicuous by reason of their peculiar plight

The wage-earning husband, known to his original employer as a capable and intelligent workman, who loses job after job and eventually drifts into a Poor Law institution or an asylum as a case of post-encephalitis is pitiable enough, equally disastrous to the home is it when the disease selects the housewife and so alters her character and outlook that, from being, perhaps, the intelligent mainstay of the home, she now becomes lethargic and melancholy, incapable of attending to her own needs, still less those of her husband and children

The results of the disease on children are certainly peculiar and deplorable in many cases, and cause considerable anxiety where the child's education and even his whole future are at stake. There is something diabolically malign in an infection which can transform a studious, well-behaved, and popular schoolboy into a lazy, vicious little terror, not fit for the company of his school-mates, and quite beyond the control of his parents at home. Most pathetic of all, perhaps, is the dribbling 'old man of 15 or so, who sits hunched up in his chair, stiff and impassive, slowly dying of Parkinsonism'

Existing measures are not altogether sufficient or suitable for many of the patients left seriously disabled, and it is held that the proper repositories for adult patients who develop mania are the certified mental hospitals. Juvenile patients placed in reformatories and industrial schools are wont to impose a great strain on the staffs

It is also difficult to find refuges for the 'troublesome and incorrigible children of older age' who, while they do not come in conflict with the law, are a source of anxiety and distraction to relatives. For a small minority of sufferers the vigorous regime of prison life for a time has been found to be the best form of treatment

There is at present no specific or efficacious remedy for encephalitis lethargica" (Recent Report of the Ministry of Health, London, Eng.)

INHERITANCE OF MENTAL DEFECT

The following letter of inquiry and the answer thereto are taken from the *British Medical Journal*, 1928, 1, 823

Sir,—Any editorial pronouncement in the *British Medical Journal* of necessity carries such weight that I am tempted to invite your attention to the annotation in your issue of April 21st (p 680) on sterilization of the feeble-minded in Alberta, where this sentence occurs "Scarcely any fact is more securely established than that it is only a small, almost negligible, minority of mentally defective persons who are the offspring of parents themselves certifiably mentally defective" On the other hand, I read in a paper on heredity of feeble-mindedness by H H Goddard, Vineland, N J (reprinted from the *Eugenics Review*, April, 1911), with regard to one single family, "Since this was written this family has been further investigated, with the result that we now know the facts concerning 319 members, of whom 119 are feeble-minded, with only 42 known to be normal" Can you assist me in reconciling the two statements — I am, etc,

D S DAVIES, M D

The two statements to which Dr Davies directs attention are not contradictory It is true that where both parents are mentally defective the offspring are almost certainly mentally defective also, and that even where one parent only is mentally defective, some of the offspring are likely to show the same characteristics Nevertheless, it is true also that in any generation only a small proportion of mental defectives are the children of parents who themselves are certifiably mentally defective, the overwhelmingly larger proportion being the children of apparently normal parents, of "carriers" who themselves are normal, or of those who suffer from mental or nervous instability or from psychoneuroses or a mild degree of mental abnormality not certifiable It follows that, for the purpose of eradicating or preventing the spread of mental deficiency, the sterilization of a small number of feeble-minded persons would be ineffective Attention may be again directed to the pamphlet on *Sterilization and Mental Deficiency* published by the Central Association for Mental Welfare

AVERTIN

In a recent lecture,* on the trend of thought in the art of therapeutics, Dr W E Dixon described a new type of general anæsthetic This was a tribrom-ethyl alcohol, known by the trade name of "avertin," the action of which had been determined precisely by Straub

* *Brit M J*, 1928, 1, 896

"It was a solid substance which at body temperature dissolved only to about 3 per cent in water, but if more concentrated solutions were required it could be employed in a suspended form To produce general anæsthesia in a patient weighing 11 stone about 10 grams of this substance was administered per rectum, this was rapidly absorbed—indeed, considerably more rapidly than water or saline solution—and the patient was anæsthetized and ready for the surgeon within ten minutes With this anæsthetic operations had been performed lasting two hours or more without pain or any subsequent discomfort to the patient, and a considerable clinical literature was already available At first, accidents happened after using it, but since the mechanism of its action had been better understood these had entirely disappeared The drug after absorption acted on the central nervous system like the commoner anæsthetics, but within a few hours it was completely broken up in the body, the bromine being converted to sodium bromide With an anæsthetic dose of 10 grams about 11 grams of sodium bromide was produced, and such an amount led to sleep lasting, perhaps, for thirty-six hours after the operation had been completed The proportion of bromide excreted depended upon the amount of sodium chloride in the blood, and varied with it, it was well known that under normal conditions when the chloride was constant the excretion of bromide was very slow, and, after a single dose, could be detected in the urine for several days It was a simple matter, however, to get rid of this excess In the case under consideration after the operation had been completed the excess of bromide should be eliminated by increasing the excretion of chlorides, this was effectively achieved by injecting from 5 to 10 grams of common salt, suitably diluted, into the rectum One objectionable feature of this form of anæsthesia, as indeed of other forms of anæsthesia, was the production of some degree of acidosis To combat this it was advisable to dose the patient before operation with sodium bicarbonate The great advantages of this method of producing anæsthesia were obvious The ease and certainty of producing the desired effect in a short time and for a long period, the absence of discomfort during administration, and the general comfort of the patient for several hours after the operation was completed, were some of them"

NARCOTIC PLANTS

In the appropriate setting of the old Physic Garden at Chelsea on June 7th, Dr W E Dixon, F R S, Reader in Pharmacology at the University of Cambridge, delivered a Chadwick Lecture on the subject of narcotic plants It was an interesting discourse on the various specimens (in the green leaf) which were on the table in front of him, and was lighted up by a genial philosophy One of Dr Dixon's observations was the curious fact that all over the world the national beverages

containing caffeine were dependent upon plants without any characteristic smell or taste. Of all the alkaloids, he said, caffeine was the most widely used by man. It was found in the leaves and beans of the coffee tree, in tea, and also, in small quantities, in cocoa. It might be said that tea, coffee, and cocoa were not narcotics, but that was because they were not taken in large enough quantities. People of all races seemed to crave for something which exerted on the brain a mild narcotic influence. This craving might be understood among highly civilized peoples, accustomed to work or play at high pressure and subject to the strain of modern life. In such circumstances anything might be seized upon which prevented the exercise for the time of the higher faculties of the mind, but why should the primitive people in Northern India smoke Indian hemp, which also produced a narcotic effect on the nervous system? To some extent it was explained, as was the taking of opium, as a social function. The natives sat round in a ring and practised this indulgence, passing into a state of languid ease, obtaining an exalted sense of their own superiority, and losing their relationship to time and space, so that the minute became an hour. Such was the result which followed the use of the essential oils exuding from certain plants. Often these oils were closely allied, though the plants producing them were very different. Who would imagine that attar of roses, eucalyptus, and turpentine had much in common? Yet when any of these was taken by the mouth the person taking it smelt of roses. In the days of imperial Rome the maidens used regularly to take a drop of turpentine so that the fragrance of the queen of flowers might cling about them. Another essential oil of very powerful properties was exuded from the nutmeg, and in the early days of tea drinking in this country the nutmeg grater was an accessory to the teapot, a little of the aromatic kernel being used to give a fillip to the tea. But, of course, the outstanding example of the narcotic plant is tobacco, whose innocent leaf Dr Dixon exhibited to his audience. Incidentally, he said, it was a fortunate thing that we did smoke tobacco and not eat it or inject it. This led him on to the generalization that in all these matters, so long as we kept away from the chemist, we were tolerably safe. Who ever heard of the juice of the vine doing any serious harm until the chemist came on the scene and practised his distillations? With opium, again, the great mischief was not done until the chemist came along and extracted its chief narcotic principle, morphine, and offered the hypodermic needle. In the same way, when tobacco was used for smoking it was relatively harmless, although Dr Dixon emphasized the evil effects of inhalation, pointing out how the CO fixed the hæmoglobin, and how even the non-smoker who had the misfortune to ride in a full-blast smoking carriage with the windows closed suffered with the guilty and had a certain percentage of his blood put out of action. But of nicotine it must

be said that its effects were marvellous in that it seemed at the same time to soothe the irritability of the supersensitive and to stimulate the dull and apathetic. How to correlate those two actions was a task which must be left to others. On the general question of tobacco smoking and of narcotic indulgence Dr Dixon remarked on the sad paradox that we seemed to get our chief pleasures in life by escaping out of life. But in smoking he thought there were some values not often considered—for example, the ritual of smoking, the lenitive effect of its rhythms, and the half-unconscious occupations it afforded—*Brit M J*, 1928, 1, 1038

MACALISTER LECTURE ON MEDICINE IN ART

The second annual lecture in memory of the late Sir John MacAlister, Secretary of the Royal Society of Medicine, was delivered at the London Temperance Hospital, under the auspices of the London Clinical Society, on June 7th, by Sir Berkeley Moynihan, Bt, President of the Royal College of Surgeons. It was a popular lecture to which nurses and a number of the lay public were admitted, and was on the subject of "Medicine in Art." Substantially it followed the lines of the lecture which Sir Berkeley Moynihan gave last autumn to the St Pancras Division of the British Medical Association. He began with the gargoyles of Notre Dame and the "Lincoln imp," and showed what interest there was in the curious deformities, no doubt shaped direct from models by the mediæval sculptor, to those who viewed them with an eye trained in medicine. Incidentally, these figures often carried horns on the head, and there was also a horn on the head of the most majestic sculptured figure in the whole world—the figure of Moses by Michelangelo, so badly placed in the church of San Pietro in Vincoli at Rome that few people realized what a masterpiece it was. The horn on the top of the head of Moses was supposed to be due to a misreading of a passage in the Vulgate. The most famous of all gargoyles was to be seen in the church of Santa Maria Gloriosa at Venice, and was the subject of an exquisite passage by Ruskin, in which he lamented the leering wickedness, the extreme of debasement, which it portrayed. But when Charcot visited this church and saw the gargoyle he said at once that it was exactly the kind of hystero-epileptic familiar to the Salpêtrière. The hystero-epileptic was considered in the Middle Ages and earlier to be the victim of "possession," and the image of him was put especially on the roofs and towers of sacred buildings to suggest that evil spirits had been driven out of the church. Another deformity familiar to very ancient artists was evidently achondroplasia, witness the representations of the great god Ptah of Egypt and Bes of Memphis—the large-headed goggle-eyed dwarf, with the short arms, the gross body, and heavy buttocks. Sir Berkeley Moynihan touched on the repre-

sensation of diseased persons in some of the great pictures by Raphael and others, and of the emotional expressions in the works of Velasquez, and he made the general remark that often some quite inferior artists, whose names were scarcely known to all, were far more correct in their details of subjects suffering from disease or deformity than were the great masters, obviously because the former stuck more closely to their models. He confessed that of all the pictures he had ever seen in Continental galleries the one which fascinated him most, and the one which he most coveted, was "The contemplation of St Jerome" in the Louvre. The Louvre authorities were said to have refused to allow this picture to be photographed, but a 100-franc note and the promise of another produced the photograph which he exhibited to the audience, it conveyed, however, little or nothing of the power of the original. In showing some photographs of mediæval statuary, Sir Berkeley Moynihan said that it was the fashion to deride many antiques to-day from the point of view of anatomy, but he believed this view to be entirely mistaken, and he instanced to the contrary the "Dying Gladiator," which brought into play in a masterly manner the accessory muscles of respiration. He concluded with some ancient works of art representing primitive surgical operations, and mentioned that the first representation of a surgical operation in a work of art in Europe—there were earlier examples in Egypt and in Asia—was a fresco at Pompeii.—*Brit M J*, 1928, 1, 1044

OBSCURE DENTAL SEPSIS

To the onlooker in medicine few things have been more impressive in recent times than the awakening of medical interest in dental and tonsillar sepsis as factors in obscure systemic infections. That there has been a gradual change of attitude on the part of the family medical attendant towards his patients' teeth will scarcely be denied. How many doctors fifteen years ago thought of toxic absorption from a tooth socket when treating a case of sciatica or of unexplained pyrexia? In the early

days of enlightenment pyorrhœa alveolaris was thought to be of prime importance, now it is apical sepsis that holds the centre of the stage, and the pulpless tooth—the "filled dead tooth"—is increasingly recognized as a menace to health. Bit by bit the evidence has been sought for, and pieced together, incriminating hidden dental sepsis as (to say the least) a predisposing cause of general disease. The fruits of the pioneer work of Dr William Hunter have thus in the course of a few years become a common place of medical practice. In this advance radiography has been of inestimable value. It is true that there is still a good deal of controversy about the interpretation of the x-ray appearances round the apices of pulpless teeth, and that all dental surgeons are not yet agreed as to the treatment of such teeth, but with improved technique and growing attention to the subject knowledge is accumulating. Fresh light on the problem, leading to something in the nature of standardized procedure, may be expected in the near future if odontologists and radiologists and pathologists continue to work hand in hand, but it is all-important, we think, that physicians and surgeons and general practitioners should regard themselves as essential members of the team. That the ophthalmologist also is concerned in this matter was preached many years ago by Mr William Lang, who had noted and reflected upon the close connection between some eye infections and dental sepsis, and at the congress last April of the Ophthalmological Society of the United Kingdom Mr A F McCallan, when discussing the ocular changes observed in association with focal sepsis, reported that one in five of a consecutive series of private patients coming merely for refraction were found on radiographical examination to have apical abscesses. In short, as Dr Patrick Watson-Williams wrote the other day, at the end of his paper on nasal and oral sepsis in the etiology of gastro-intestinal and pulmonary diseases, "in medicine there is but one field which ever calls for team work"—*Brit M J*, 1928, 1, 1036

"Let the first satisfying of appetite be always the measure to you of eating and drinking, and appetite itself the sauce and the pleasure. Thus, you will never take more food than is necessary, nor will you want cooks, and you will be contented with what ever drink falls in your way"—*Epictetus*

"Crafty men condemn studies, simple men admire them, and wise men use them, for they teach not their own use, but that is a wisdom without them and above them, won by observation"—Lord Bacon

Abstracts from Current Literature

MEDICINE

Vingt Années d'Expérience de l'Endocardite Infectieuse à Evolution Lente (Twenty Years' Experience with Chronic Infectious Endocarditis) Syllaba, L, *Annales de Médecine*, 1928, **xxiii**, 430

The malady studied and analyzed by Syllaba in this paper is characterized by a typical clinical evolution, by, frequently, positive blood cultures, and by a fatal issue. It was known to Osler in 1885, and was described by him under the name "chronic infectious endocarditis." It was separated from the other endocarditides, on bacteriological grounds, by Schottmüller in 1910.

Syllaba bases his conclusions on a very full study, over some years, of 46 cases, in 33 of which the clinical diagnosis was confirmed by autopsy. In 17 cases examined bacteriologically, 10 (59 per cent) showed streptococci in the blood. Commenting on the bacteriological findings, Syllaba considers that more stress should be laid on the clinical course and post-mortem findings. Chronic infectious endocarditis, in his opinion, is a septic condition, tending towards death, to be distinguished from a chronic benign endocarditis with bacteraemia and without metastases, tending towards healing. The disease is of slow evolution. It may last weeks, months, or even a year or two. Fever may last weeks and may be intermittent. Its duration has no particular importance in the matter of diagnosis. The chief feature in the clinical picture is the repeated occurrence of emboli and metastases. In the presence of embolic manifestations a negative blood culture should have no weight.

The following points are of value in arriving at a correct diagnosis: (1) A history of one or more attacks of acute rheumatism, with the occasional development of signs of cryptogenic septicæmia, should suggest the possibility of chronic endocarditis, (2) The presence of severe anaemia with a sub-icteric tint of the skin (*café au lait*), (3) The appearance of a diastolic murmur, perhaps transitory, at the aortic or mitral orifice, (4) Hypertrophy of the spleen (usually present), (5) Cutaneous hæmorrhages, pemphigus, erythema, circumscribed and fleeting oedema, (6) Epistaxis, hæmoptysis, or hæmatemesis, (7) Pain in the thorax or abdomen (from infarction), (8) Pain in the limbs, most frequently periarticular, (9) Retinal hæmorrhages, (10) The sudden onset of aphonia with stridulous respirations, (11) Hæmaturia, (12) Cultures of the blood and urine, (13) Monocytosis in the blood with a deviation to

the left of the nuclear index, (14) Gangrene of one of the extremities from arterial occlusion, (15) Hemiparesis, hemiplegia, fleeting aphasia, etc.

In spite of this imposing list of suggestive features the diagnosis will still sometimes be in doubt. The features detailed above are indications of the presence of a septicæmia, they do not necessarily indicate endocarditis. The final test comes in the daily careful observation of the clinical course. Changes in the heart function, occurring under observation, will be of paramount importance.

A. G. NICHOLLS

Two Cases of Hæmaturia Caused by Insulin Treatment Laurence, R. D., and Hollins, A. S., *Brit. M. J.*, 1928, **i**, 977

The production of hæmaturia by insulin treatment is rare enough to make it worthy of note. The authors give details of two such cases. The first was that of a youth of nineteen years, who developed mild diabetes in August, 1927, which was controlled by diet alone. On November 7th he developed tonsillitis and two days later was admitted to hospital in a pre-comatose condition. He received 120 units of insulin that day, which completely abolished the glycosuria and left only a trace of ketonuria. On the two following days he received 50 units a day, and on the second day hæmaturia was noticed. This lasted for 24 hours and re-appeared three days later for one day. Insulin (evidently) was given all along and was finally discontinued in two weeks' time.

Apart from the blood, the urine showed no abnormality at any time and kidney function tests were normal. There was no complication other than a well-compensated mitral lesion, due to previous rheumatism, and no history of previous hæmaturia, either in himself or his family. The pharyngitis was almost better when the blood first appeared.

The second case was that of a boy of eighteen, a severe diabetic, who was admitted with severe ketosis, which cleared up with large doses of insulin. Obvious hæmaturia appeared on the sixth day of insulin treatment (25 and 18 units morning and evening) clearing off within the day. As in the first case, the renal tests were normal and no septic focus was discovered nor any factor to account for the blood other than the insulin.

The authors can find reports of but seven other such cases. The only factor common to these seems to be that the hæmaturia appeared while large doses of insulin were being given.

It is pointed out, however, that more details are needed as regards the degree of ketonuria present, since it is known that ketone bodies are an irritant to the kidneys and the increased excretion caused by insulin might be responsible. In the two cases under consideration ketosis had been severe, but was practically absent at the time of the hæmaturia.

There seems to be no reason for thinking that the hæmaturia is any reason for discontinuing insulin, either temporarily or permanently.

H. E. MACDERMOT

Tod Infolge Bluttransfusion (Death Following Blood Transfusion) Biesenberger, H., *Wiener klin Wchschr*, 1928, xli, 923

The author states that the fatalities following blood transfusion, according to the reports given in the literature, were attributable to hæmolytic and agglutination. He reports a case in which neither occurred.

His patient was a female, aged 34 years, suffering from severe pernicious anæmia and a paralysis of the lower extremities due to myelitis. One hundred and fifty cubic centimetres of blood had been transfused, when the patient complained of sudden sharp stabbing pains over the heart. A preliminary pallor was quickly succeeded by severe cyanosis of the face, soon spreading over the whole body, together with a feeble pulse.

The transfusion was immediately discontinued, CO₂ was administered, as well as heart stimulants. In half an hour the patient had recovered sufficiently to be taken back to the ward. Then her condition again became serious, delirium set in, followed by coma. Death occurred in one hour from the beginning of symptoms, with all the signs of acute cardiac failure, including œdema of the lungs.

At the autopsy, in addition to the usual signs of pernicious anæmia and myelitis, an old stenosis and insufficiency of the mitral valve was found.

As a rule, the presence of an organic lesion of the heart is not regarded as a contra-indication to blood transfusion, but this case shows that there are exceptions. The severity of the heart lesion, the degree of compensation, and the accessory or accidental factors, in this case the pernicious anæmia, should be taken into account.

A. G. NICHOLLS

Shoe Dye Poisoning Aikman, J., *Am J Dis Child*, 1928, xxxv, 1038

This is a report of three cases of poisoning by shoe dye in children, who seem to have a susceptibility to its influence. The outstanding symptom in this type of poisoning is general cyanosis, which may be as extreme as it is in

cardiac disease. It is accompanied by general weakness, headache, vomiting, and general prostration, the symptoms beginning in from one-half to several hours after the shoes are put on. The condition lasts only a few hours, but deaths have been reported by some observers.

The poisoning is caused by the dye applied to tan shoes to alter their colour. Absorption of the dye takes place through the unbroken skin, and is more apt to occur if the shoes are damp. Removal of the shoes causes decrease of the cyanosis, but it may last several hours longer. There is some doubt regarding the poisonous element in the shoe dye, but it is generally held that it is either the aniline, or the nitrobenzene, which is the solvent used for the dye. Both these are benzene derivatives of the coal-tar series, aniline being reduced from nitrobenzene.

The packages in which the dye is put up contain a caution not to use dyed shoes until twenty-four hours after they have been finished. In one of Dr Aikman's cases, however, a boy of six years old, the shoes had been dyed four days before, and, though he improved after removal of the shoes, the cyanosis returned next day when the shoes were worn again. Another case is reported of a girl, aged nine, who showed a return of the poisoning when the shoes were worn nine days after the first attack.

The treatment consists of a thorough bath and a rest in bed. Dyed shoes should be well aired several days before being worn by children.

Gelatin in Medicine Beal, G. D., and Neff, A., *J Am Pharm Ass*, 1928 vol xvii

The authors find that the first extensive use of gelatin was during the French Revolution, when the Government, backed by the Academy of Medicine, supplied gelatin soups to the poor. One manufacturer of gelatin named Gannal used his family for experimental feeding with gelatin, but after a time their health failed on their diet of gelatin and bread and water. It was Voet, however, in 1870, who first established the fact that gelatin always spares protein to some extent, but is less complete than protein.

Edible gelatin is prepared commercially by steam-cooking specially prepared bones or skin. The material is washed, then treated with lime for thirty days or more, re-washed, neutralized and heated in open vessels with steam coils. By this method the original protein, ossein or collagen, is broken down into gelatin. The solution is then concentrated, filtered and clarified.

Gelatin is used in medicine chiefly in connection with feeding. Its use in ice cream is practically universal, about 0.5 per cent is used to give the cream a smooth velvety texture. It lends itself also especially to making many attractive varieties of salads and desserts, which

is of considerable importance from the dietician's point of view

SURGERY

Benign Prostatic Hypertrophy Hunt, V. C., *Surg., Gynec. & Obst.*, 1928, *xlvi*, 769

The treatment of benign prostatic obstruction during recent years has led to the development of certain principles which have added to the reduction of the mortality rate and to the safety of surgical treatment and these principles have been combined by the internist urologist and the surgeon.

The stresses and strains of life result in degenerative changes in the cardiovascular system. In prostatic obstruction the renal excretory mechanism is directly affected resulting in renal insufficiency, but renal insufficiency may be otherwise organically impaired by other diseases of the cardiovascular system. Willius has concluded that the incidence of cardiovascular disease is higher with prostatic obstruction than with other diseases during the same decades indicating that cardiovascular disease is aggravated by persistent urinary retention.

Adenomatous hypertrophy comprises about 85 per cent of benign obstructing lesions the remainder being of an inflammatory nature. On rectal examination, prostatic fullness is encountered in 50 per cent of men fifty years of age but the symptoms of obstruction are relatively rare at that age or under. A small gland may produce obstruction with complete retention while on the other hand, a huge gland may provide adequate urethral passage. It is the moderate-sized gland which is usually productive of retention frequency and difficulty.

Cystoscopic examination is not recommended in all cases of prostatic obstruction. Braasch has followed the principle of cystoscopic examination in those cases in which observation on digital examination do not explain the symptoms. All cases should be given careful urological consideration for too often normal prostate glands have been removed for symptoms higher up in the tract. Retention and residual urine definitely due to the prostate, form the true indications for prostatectomy. The patient with prostatic obstruction is as a rule a poor subject for immediate operation, and the merits of preliminary treatment have been definitely established. Drainage of the bladder is of prime importance and cystostomy should give place to the permanent indwelling catheter, and should be continued until the cardiovascular-renal reserve has been restored to a period of safety. This period requires from ten to twelve days and is the method of choice, for it facilitates the one-stage visualized operation. Suprapubic drainage is necessary under the condi-

tions of associated vesical lesions such as stones and diverticula and in those cases of marked renal insufficiency requiring long periods of drainage. The intolerance of the indwelling catheter also is an indication, but this occurs only in about 6 per cent of the patients.

The two-stage suprapubic prostatectomy is the procedure of choice under certain circumstances but the one-stage visualized operation, preceded by catheter drainage is gradually becoming preferred and in the series studied was the method adopted in 72 per cent of the cases. Regional anaesthesia has properly displaced general anaesthesia in this field of surgery, and minimizes post-operative renal depression and pulmonary complications. The accepted contraindications to prostatectomy are, cardiac decompensation, coronary sclerosis with evidence of marked myocardial injury and advanced malignant hypertension. The results of prostatectomy are very gratifying about 85 per cent of the patients are completely, or almost completely relieved of their symptoms.

The author, in summing up, emphasizes the fact that the case of benign prostatic obstruction is largely medical; a surgical condition is present but there are aspects which may best be appreciated by the physician and it is through the combined effort of the internist urologist, and surgeon that the patient can be operated on with the minimal risk and assurance of the best functional result.

R. V. B. SMITH

The Diagnosis of Branchial Cyst Bailey, H., *Brit. M. J.*, 1928, *i*, 940

It is common to find a branchial cyst mistaken for necrotizing tuberculous cervical glands, for branchial fluid on being aspirated looks exactly like tuberculous pus and brings forth on bacteriological examination a report in keeping with that of tuberculosis namely "No tubercle bacilli found cultures sterile." In about 10 per cent of cases tubercle bacilli are found in tuberculous pus but the author quotes a case in which a branchial cyst was removed showing the characteristic stratified squamous epithelium upon a basis of lymphoid tissue while the fluid aspirated before operation showed numerous tubercle bacilli.

Caseating tuberculous glands are exceedingly common while branchial cyst is comparatively rare. Branchial cyst makes its first appearance in early adult life, curiously with an abrupt onset, after which the cyst slowly increases in size. Recurrent attacks of inflammation are usual. The cysts are nearly always related to the upper third of the sterno-mastoid around the anterior border of the muscle. But as the muscle becomes thinned and flattened over the cyst this relationship is seldom clear until the muscle has been rendered taut. To confirm the

diagnosis of branchial cyst a little of the fluid is aspirated, a drop of aspirated fluid placed on a slide, the slide examined with a one-sixth power lens, and the presence of cholesterol crystals at once makes the diagnosis certain

Branchial cysts should be completely removed by dissection. They often run deeply into the neck, and may extend upwards as far as the base of the skull. It is desirable to remove the cyst intact, for if the cyst bursts the dissection is difficult. The author believes that the following technique simplifies the operation after carefully cleaning the superficial aspect about half the contents of the cyst are removed by aspiration, the puncture hole being covered with a piece of gauze, the gauze and cyst wall are then picked up with a pair of sponge-holding forceps, gentle traction is made in various directions, and the cyst wall is cleared by gauze and blunt dissection, aided here and there by some sharp dissection. Using these means the intact cyst may be completely enucleated.

GYNÆCOLOGY AND OBSTETRICS

An Analysis of Thirty-Two Cases of Ectopic Pregnancy and Three Suspected Ectopic Pregnancies Allen, E, *Am J Gynec & Obst*, 1928, xv, 540

Anything which interferes with descent of the ovum, whether it be infection or infantilism, predisposes both to sterility and ectopic pregnancy. In this study, the average age of the patients was 30.8 years, and the percentage of relatively sterile cases in the series was 71.7.

Irregular bleeding or spotting was the most constant symptom noted, but in one-third of the cases there was no period of amenorrhœa. As a rule the bleeding was not profuse and was often referred to by the patient as a normal period, until definite questions were put to her. Lacerating pain was not noted, but cramps in the lower abdomen, referred down the thigh, were present in 31 per cent. Seven-tenths of the cases showed a leucocytosis of 10-20,000, with a temperature range of 98° to 100° F.

Treatment consisted of a diagnostic curettage and colpotomy. If blood was obtained, and the tube was free, it was removed vaginally. The abdominal operation was advisable only when the pelvis was full of blood or the tube adherent. As a means of diagnosis in doubtful cases, the colpotomy incision was an invaluable aid.

Observations on Certain Features of the Pathology, Symptomatology, and Treatment of Retroversion Cooke, W. R. *Am J Gynec & Obst*, 1928, xv, 493

In a study of 1,153 cases of retroversion,

occurring in the gynæcological service of the John Sealy Hospital, several observations of interest were made.

Retroversion causes a congestion of both the uterine and ovarian veins, producing a large, boggy uterus, which microscopically shows perivascular fibrosis in the myometrium and hyperplasia of the endometrium. This stage is characterized by menorrhagia. In cases of long-standing retroversion the menstrual interval becomes irregular, due to fibrosis of the ovaries, the flow being therefore irregular and profuse. In very advanced cases, the ovary becomes so fibrotic, that amenorrhœa may occur. The individual symptomatology depends on the balance between the uterine and ovarian dysfunction.

As regards fertility, patients with menorrhagia showed a decreased fertility, but once the ovum became embedded, abortion seldom occurred. Those with delayed interval were less fertile and were more apt to abort, since the vitality of the ovum was low.

So far as treatment is concerned, simple measures, such as the knee-chest posture, a pessary, etc., are indicated in puerperal retroversions, and they may be used as a test to see if the symptoms are relieved, before resorting to operative procedures. When operation is necessary, the technique used is that of sewing the lower anterior surface of the uterus (well below the fundus) to the anterior parietal peritoneum by means of three sutures. At first, the uterus lies out of the pelvis, but within a few weeks it assumes an almost normal position.

ELEANOR PERCIVAL

The Influence of Disease of the Thyroid on Menstruation Hill, H. G., & Smith, J. F., *J Obst & Gynec Brit Emp*, 1928, xxxiv, 701

The relation between thyroid and ovarian activity has been recognized for some time. In some forms of thyroid disease menstruation is suppressed, while in others it is increased. In a study of 300 cases of thyroid dysfunction, in which basal metabolic rates were determined, the following conclusions were reached:

1. Cretinism—If untreated before puberty menstruation is usually established late. If properly treated the onset and type of menstruation are normal.

2. Hyperthyroidism—The periods tend to be scanty and irregular and, in very severe cases, may be suppressed.

3. Hypothyroidism—Here menorrhagia is the rule.

4. Simple Adenoma—If the basal metabolic rate is within normal variations, menstruation is not disturbed.

PÆDIATRICS

The Etiology of an Epidemic of Enteritis Associated with Mastoiditis in Infants Dick, G F, Dick G H, and Williams J L, *Am J Dis Child*, 1928, xxxv, 955

These authors report an outbreak of enteritis associated with mastoiditis in a foundling home. The epidemic is interesting because it was due to a primary intestinal infection with the Morgan dysentery bacillus, and was regularly complicated by otitis media and mastoiditis. In the more chronic cases, the subsidence of the acute intestinal inflammation and the progression of the mastoid lesions, which resulted in necrosis of the petrous portion of the temporal bone or sinus thrombosis and meningitis, obscured the intestinal origin of the disease.

"That this epidemic of enteritis associated with mastoiditis in infants was primarily an intestinal infection is shown by the results of bacteriological examination in which the Morgan dysentery bacillus was found, and by the fact that the epidemic was controlled through discarding all foods which were not fresh and which could not be boiled, and the adoption of measures to prevent the transfer of intestinal bacteria by the fingers of nurses."

R. R. STRUTHERS

The Sex Factor in Infantile Tetany, Bakwin, H, and Bakwin, R M, *Am J Dis Child*, 1928, xxxv, 964

This paper reviews the sex incidence of tetany in 136 cases at the Bellevue and Babies' Hospital, New York. Of these 68 per cent were boys and 32 per cent girls. Apparently, infantile tetany is twice as common in boys as in girls. This indicates a predisposition on the part of males for tetany comparable to that of females for chorea. This predisposition is even more marked below the age of 8 months. The increased severity of the disease in males is striking. All the deaths in the series reported occurred in male infants.

R. R. STRUTHERS

PATHOLOGY

Pulmonary Asbestosis in South Africa, Simson F W, *Brit M J*, 1928, i, 885

It has been known for some time that workers exposed to the dusty atmosphere attendant on the preparation of asbestos materials suffer pulmonary disabilities, but very little has as yet been written concerning the pathological changes in lungs caused by the asbestos itself.

Dr Simson now publishes details of four patients in whom certain special pulmonary changes were noted in conjunction with their having been employed in asbestos mines in

Southern Rhodesia. In two of these there were connective-tissue changes which were different from those found in tuberculous conditions, and were also in contrast to the sharp definition of silicotic nodules, but the most striking feature common to all four was the occurrence of numerous golden yellow bodies which were found either embedded in the fibrous tissues, lying free in the alveoli, or contained in phagocytic cells. They varied in shape, but usually had rounded or club-like ends, with a segmented body tapering to a finely pointed tail. They were non-refractile to polarized light, soluble in strong acids, and on being heated turned black and tended to lose their outline. They gave a well marked Prussian blue reaction with hot diluted hydrochloric acid and potassium ferrocyanide. These and other tests led to the conclusion that the bodies contained a large percentage of iron.

Comparison was made with sections of lungs from a large number of miners on the Rand who had died from silicosis and tuberculosis, but none of these could there be found any such bodies as those described. Confirmatory evidence of their connection with asbestos dust was obtained from the lungs of a guinea pig which had been exposed to the dust under experimental conditions, the presence of the golden yellow bodies was easily demonstrated in the animal.

These bodies therefore seem to be undoubtedly associated with asbestos, not as it is mined in open quarries but in the mills where waste rock is crushed for extraction, and where the asbestos undergoes carding and spinning.

As regards the association of asbestosis with other pulmonary diseases, evidence is being accumulated to show that phthisis occurs with sufficient frequency among asbestos workers to warrant the suggestion that this occupation serves as a predisposing factor to a certain extent.

H. E. MACDELMOT

Blood Vessels in the Valves of Normal Hearts Ritter, S A, Gross, L, and Kugel, M A, *Am Heart J*, 1928, iii, 433

These workers have studied 700 hearts by their injection method to determine the existence or otherwise of blood vessels in the valves. In this series there were 14 cases in which both the study of the gross and microscopic appearances, and the clinical history of the patient, showed the heart to be apparently perfectly normal, and yet to present blood vessels in some of the valves. This fact and other reasons given make it highly improbable that the vascularization of the valves in these 14 normal hearts owes its origin to inflammation, or that the vessels are other than embryonic vestiges.

M. E. ABBOTT

THERAPEUTICS

The Treatment of Malignant Disease by Colloidal Lead Wyard, S, *Brit M J*, 1928, 1, 838

Dr Wyard felt that the success claimed for the treatment of malignant disease by injections of colloidal lead warranted a careful investigation of the method, and he now presents a report of his work on the subject. Working in association with Dr Lorna King, he treated a series of 88 patients by this method, but, in order to compare his results with those of Dr Blair Bell, he omits details of 32 of these cases, in whom he used a preparation of colloidal lead hydroxide which differed slightly (although, as he thought, advantageously) from that used by Dr Bell. Little importance is attached to the statement that satisfactory results could only be obtained by preparing the lead in a particular manner, since the method of preparation was apparently changed several times in Liverpool.

Fifty-six cases were treated strictly by the Liverpool method. It was impossible to obtain supplies of the colloidal lead, and Dr Wyard therefore prepared his own by means of a special electrical apparatus. He lays emphasis on the fact that even with the greatest care and attention to details the preparation is very unstable and cannot be prepared in bulk for use at a later date.

Most types of malignant disease were treated, epithelioma, carcinoma, and sarcoma. In every case the disease was at an inoperable stage, or was recurrent after operation. It was not easy to obtain patients who fulfilled the conditions necessary for an investigation of this type, since they were either receiving radiation, or some other form of treatment which would vitiate conclusions as to the lead treatment, or else they

were too far gone for any form of treatment.

Some difficulty was experienced in establishing the dosage and the interval between treatments. Very severe reactions were found to follow what seemed safe quantities. The interval could only be decided by clinical experience. No reaction in the growth itself could be detected with certainty, except that in two cases the mass presented pain and swelling.

The paper goes into the various changes produced by the lead, in great detail, and should be consulted for such.

Autopsies were made in 17 of the cases, with remarkably constant findings. In no case was there any sign of retrogression of the growth, in every case the mass was larger than at the beginning of the treatment. In nearly every instance the brain showed a marked degree of superficial oedema, the liver, extreme fatty degeneration, and the kidneys some degree of desquamation of the convoluted tubules. Dr Wyard feels justified in ascribing these constant changes to the toxic action of the lead.

His final conclusion is that there is no support for the statement that colloidal lead exerts any beneficial influence on the progress of a malignant growth. Of the 56 patients treated, only one showed definite improvement, and in this there was some doubt regarding the malignancy of the gland involved (a small supraclavicular node following amputation of the breast one year previously). On the other hand, of 40 patients who received enough treatment to warrant the expectation of some benefit ("if any ever occurs"), 22 died, 11 were clearly worse, 6 showed no change either way, and only one improved.

In addition to this he points out that the method is difficult and dangerous.

H. E. MACDERMOT

To Promote Sleep—The Institution of Civil Engineers held a *conversatione* at the Institution, Great George Street, Westminster. An exhibit which excited much interest was the Yarrow Hyde bed. This was shown by Sir Alfred F. Yarrow, for whom it was constructed in order to promote sleep. It was explained that during a journey last autumn from Vancouver to Montreal he found that when the train was in motion he slept far better than when it was still. He tried experiments similar to those which he made many years ago on the vibration of ships, and he determined

to repeat, if possible, in an ordinary bed, the vertical movements of a train. He asked the National Physical Laboratory to study the subject. Mr Hyde, one of the engineering staff, provided a solution of the problem, and the result is the Yarrow Hyde bed, which, it is stated, has a movement that corresponds so far as practicable in amplitude and frequency to what was found in the train on the Canadian Pacific Railway. A simple crank mechanism worked by an electric motor provides a gentle rise and fall of the bed at its head.

Obituaries

Dr Charles Magee Anderson, of Toronto, Director of Laboratories, Ontario Department of Health, died suddenly on July 19th in his 38th year, at the home of his father in law, George E. Firth of Burrill's Rapids on the Rideau River. He was a native of Ottawa, the son of the late William and Mrs. Anderson. He received his education at the public schools and Ashbury College, at McGill he received the degree of M.D., C.M., and at Johns Hopkins University he obtained the diploma of D.P.H. He served overseas in the Imperial Forces with the Royal Sussex Regiment as medical officer during the Great War. For eight years he had been in his provincial position at Toronto and was widely known in Ontario in connection with his public health work.

Dr J. N. H. Campeau. It is with regret we announce the death of Dr J. N. H. Campeau, which occurred at his residence, 3672 Lasalle Boulevard, Verdun, on July 11, 1928. Dr Campeau was born at Rigaud on July 17, 1868, was educated at Rigaud, and graduated in medicine from Laval University in 1889.

Dr Peter Anderson Dewar died on April 7, 1928, at his residence in Walkerville, Ont. He was born on a farm in Lambton County on September 4, 1859, and received his early education in the public schools of that county and in the Sarnia Model School. His first profession was that of teaching, and from that he stepped into medicine, graduating from Trinity Medical School in Toronto in 1885, with first class honours. He began practice in Essex, Ont., and remained there for eleven years, during which time he built up a very extensive clientele, and also took an intense interest in the civic affairs of the town. In 1896 Dr Dewar moved to Windsor, where he practised until a few months before his death, when ill health compelled him to moderate his activities.

During his professional career he started a number of young graduates on the road to success. His favourite maxim to them was "Be well known as a physician," and he himself always kept this ideal in mind and lived up to it fully, with the result that he was widely known as one of the most brilliant and successful physicians of western Ontario.

Two years ago he was given a dinner and a presentation which testified to the high regard in which he was held by his fellow practitioners, as well as by the community in general. This marked the completion of forty years active practice in Essex County, and was attended by about one hundred representative citizens of the border cities.

He is survived by his wife, (née Anne K. Nesbit) and five daughters.

Dr Andrew Love, who died at New Glasgow on June 16th, was one of the best known practitioners in Nova Scotia. He graduated at McGill in 1891, and after a year or two at country practice located at Sydney Mines. Here he quickly developed a large practice and identified himself prominently with community affairs. On the outbreak of war he volunteered for overseas service, and was soon sent to France, where he was engaged until hostilities ceased.

On returning home, he located at New Glasgow, and was soon well established there. For two years or more he had been in indifferent health, possibly as a result of war service, but the illness which resulted in his death was of only a few days' duration.

Dr Love was very popular, served in the Town Council of New Glasgow, was Commissioner for Pictou

County of the Boy Scouts Association, and on one occasion accepted a nomination to contest Pictou County in the interests of the Conservative party, although he resigned before the election came on. He enjoyed an enviable reputation as a practitioner, and was highly esteemed by all classes and creeds.

Dr Daniel Angus McAulay, of Baddeck, died recently under unusually sad circumstances. Dr McAulay, who was one of the younger members of the profession, graduated from Dalhousie in 1910. He was one of those who responded early to his country's call, and served under the colours almost throughout the war with credit. He settled in Baddeck soon after his release from military duty, and quickly won a place in the esteem and affection of that charming village. A few days before his death, while operating on a septic case, he became infected and it soon became evident that his condition was very serious. He was removed to hospital at North Sydney, where every effort was made on his behalf, but death occurred on June 16th.

Hon. Dr L. P. Normand, ex-mayor of Three Rivers and Minister in the Meighen cabinet of 1921, died at his residence, Three Rivers, on June 27th, after a short illness.

Hon. Louis Philippe Normand, M.D., was a prominent physician and had been head of the Medical Council of Canada. Born at Three Rivers, Que., on September 21, 1863, the son of Telesphore E. Normand and Alphonsine Giroud, he was educated at LaSalle Academy, St. Joseph Seminary and Laval University, graduating as M.D. from the latter in 1886. Later he pursued his medical studies in the United States, Great Britain, France and Italy.

Dr Normand always took a keen interest in municipal affairs, and was mayor of the city of Three Rivers for four consecutive terms. When Right Hon. Arthur Meighen reorganized his cabinet before the general election of 1921 Dr Normand was sworn in as President of the Privy Council. He contested Three Rivers-St. Maurice in the Conservative interest, but was defeated and went out of office with the resignation of the Government in December, 1921.

On February 5, 1891, Dr Normand married Mlle. Graziella H. Beaulieu, daughter of Charles Beaulieu, of Sorel, Que. The children are Philip, a priest, Hortense Hudou, Louis P., Jeanne (married to Georges A. Gouin), Joseph, Margaret, Jean and Pierre.

Dr Normand enjoyed extraordinary popularity in his district. His professional attainments were of a high order and had been widely recognized by medical associations and institutions, not only upon this continent but in Europe.

DR NORMAND: AN APPRECIATION

With the death of Dr L. P. Normand, of Three Rivers, which happened the last days of June, we have to bewail the loss of a leading figure in our Canadian profession. Dr Normand was not only a brilliant surgeon in his native Province of Quebec, but a leading figure in our profession far and wide in Canada.

Born in 1863, he graduated after eight years of classical studies at Laval University, well prepared for the high positions he was later to occupy. We all know the importance attached in England and Scotland, as well as on the continent, to a good basis for future medical studies and the high opinion in which classical studies are held as a solid *groundlage* for further studies. He graduated B.A. with honours, and later completed his medical studies in New York and Paris, as well as London.

He settled down in Three Rivers, the centre of a most active industrial area, that of the St Maurice River, a thriving little city of over 30,000 souls to day. His fame as an able and conscientious surgeon grew rapidly and people flocked to him from all over the vicinity as well as from far away.

President of the local medical society and President of the Second Congress of French speaking Physicians of America, still higher honours awaited him. Soon he was elected President of the Province of Quebec College of Physicians and Surgeons, and later was called to the high position of President of the Medical Council of Canada.

Always of broad ideas, of a congenial mind, well read, well travelled and well trained in his profession, he had a host of friends far and near.

After the conflagration which swept his native town, he was called to the leadership of the City Council and through his energy and enterprising spirit recreated a new city, which all motorists from Montreal to Quebec admire. He even entered the political field and was Minister in the Meighen Cabinet.

Honours came to him plentifully, and particularly

did he prize his elevation as Knight Commander of the Order of Gregory the Great by the Pope for services to the community, and Officer of the Legion of Honour by France for his devotion to the cause of education, public as well as medical.

The disappearance of such men is a loss not only to their own community but also to our profession.

He laboured well and deserved well.

EGG ST JACQUES

Dr E Virolle The death occurred suddenly, on July 4th, at his residence, 116 Laprairie Street, of Dr Eugene Virolle, well known teacher at the University of Montreal, aged 54 years. He was born in 1874 in Montreal, and was prominent in medical circles. At the time of his death he was Professor of Anatomy at the University of Montreal.

Dr John Percy Waddy died in Toronto on June 25th in his 79th year. Dr Waddy was born in Ireland and received his education there, coming to Canada forty years ago. After many years' practice in Muskoka Dr Waddy moved to Mount Albert, and, later retired to Toronto where he had lived up to the time of his death.

GREAT BRITAIN

The Leishman Memorial

On June 2nd, two years after his death, a memorial tablet to Lieut General Sir William Leishman, KCB, FRCS, was unveiled in the chapel of the Queen Alexandra Military Hospital, Millbank, and following the ceremony another tablet was unveiled in the pathological laboratory of the Royal Army Medical College. A brief dedicatory service was conducted by the Chaplain General of the forces. These tablets form part of the memorial subscribed for by the officers, non-commissioned officers and men of the Royal Army Medical Corps. The main portion consisted in the medal which had been struck and the prizes offered for competition to officers and men of the corps. It was stated at the unveiling that, while the memorial in the chapel was intended to commemorate Sir William Leishman as a great Director General, the memorial in the laboratory recalled him as a teacher, an eminent man of science, a research worker, and a discoverer of world-wide renown. Although the memorial had been erected at Millbank, it was only right to say that much of Leishman's work was carried out elsewhere. The original discovery of the parasite of kala-azar was made in the old laboratories of the Army Medical School at Netley, there also Leishman prepared the stain which bore his name, and it was there he was associated with Almroth Wright and David Semple in work on the typhoid vaccine—work which was subsequently to develop to such a remarkable extent in the army, to be the means of saving thousands of lives of British soldiers in India and elsewhere, and to be adopted and adapted by practically every nation in the world. As professor of pathology Leishman put in very strenuous work.

General Harvey described his teaching carried on in that very room, and his gradual attainment to the position of a national figure in the field of research, so that there was hardly a piece of organized medical research with which he was not connected, but he added that Leishman was not a scientist so absorbed in his pursuit as to be oblivious of the claims of family and friends. He was a devoted husband and father, and nothing would have pleased him more than the high degrees in science recently obtained by two of his daughters and the academic career of his son. "Tablets

will crumble in the course of time, but the name and fame of William Leishman will be passed on," said General Harvey in conclusion, "from generation to generation." The tablet in the college records the fact that Leishman carried out his researches on typhoid, kala-azar, relapsing fever, and other diseases in that place, where he taught from 1907 to 1913. The tablet in the chapel recites his many military, medical, and academic distinctions. The ceremonies were attended by Lady Leishman and other members of the family, and by a large number of past and serving officers, while among others present were Sir John Rose Bradford (President of the Royal College of Physicians), Dr Andrew Balfour, Sir Almroth Wright, Sir David Semple, and many more who came into close touch with Sir William Leishman's life and work.

A Relic of David Livingstone

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow on February 6th, Mr G H Edington, the president, in the chair, the surgical pocket case used by David Livingstone during his daily work in Africa was presented to the Faculty by Dr Freeland Fergus, on behalf of Mr Hilliard, surgical instrument maker in Glasgow, to whom the relic belonged, but who was prevented by his state of health from attending the meeting. In the course of a letter from Mr Hilliard it was recalled that Dr Livingstone had been born at Blantyre, some seven or eight miles distant from the hall of the Faculty, and had obtained his licence to practise from the Faculty of Physicians and Surgeons at Glasgow. Through Mr Hilliard's influence, the instrument case which belonged to Dr Beatty, R.N., the surgeon on board the *Victory* at the battle of Trafalgar, had been, some years ago, presented to the Royal Faculty of Physicians and Surgeons. Dr Fergus mentioned that Mr Hilliard had been the close friend of Dr Livingstone's son, Mr W Oswald Livingstone, from the old High Street College days. In 1909 Mr Hilliard had followed the steps of the explorer in many districts, including the flourishing town of Livingstone and other places bordering on the Zambezi. Many offers had been received for the relic from wealthy collectors in America, London, and Scotland. Dr Fergus added that

although Mr Hilliard was not a member of the medical profession, he had been connected with it all his life, being born in the Royal Infirmary, where his father, as cutler and instrument maker, had at that time an official residence

Sir Ronald Ross as a Pupil

Sir Ronald Ross has been the recipient, at the hands of Lord Leverhulme, of the Harben Gold Medal of the Royal Institute of Public Health. This medal, which has been won by such famous men as Pasteur and Lister, is awarded every three years for "eminent services to public health, irrespective of nationality." Sir William Smith, principal of the Royal Institute of Public Health, recalled during the simple ceremony that Sir Ronald Ross was one of his pupils. "He was one of the most

difficult men with whom I have had to deal," he said. "In fact, I thought he would never pass the examination for public health. Now he has long left his teacher behind."

The Dawson Williams Memorial Fund

The Committee having in charge the duty of arranging for some suitable memorial to the late Sir Dawson Williams, Editor of the *British Medical Journal*, report that a sum somewhat in excess of £500 has been collected. Trustees have been appointed who have suitably invested this sum. It has been recommended that the memorial take the form of a Prize, to be awarded every two years, or at longer intervals, for the best work on Pædiatrics which has appeared since the last award.

NOVA SCOTIA

The graduating exercises of the training school of Kings Memorial Hospital, Berwick, were held in June. The principal speaker was Dr H. K. MacDonald, of Halifax, whose address to the graduating class was replete with sound advice.

On June 12th, eleven nurses graduated from St Joseph's Hospital, Glace Bay.

It has been decided to rebuild the Amherst Hospital, the destruction of which by fire was mentioned last month, on the site of the old building. It has been found that the old walls can be utilized to a considerable extent. Several architects are interested in the preparation of plans for the new building.

It will be remembered that the nursing staff had no opportunity of saving any of their effects on account of the necessity of removing the patients. The citizens of Amherst raised a subscription and each nurse has been presented with a cheque for one hundred dollars towards reimbursing her loss. Investigation by the fire marshall led him to the opinion that the fire was due to defective electric wiring.

At the annual meeting of the Registered Nurses Association of Nova Scotia, held in Yarmouth in June, Miss Catherine M. Graham, of Halifax, was elected to the presidency.

The Massachusetts Halifax Health Commission ceased its activities at the end of May. It is understood that the Victorian Order of Nurses will take over some clinics which were conducted by the Commission in the north end of the city. The public health nursing service maintained by the Commission is not likely to be continued.

Dr T. M. Siemewicz, who has been Acting Executive Officer for the Massachusetts Halifax Health Commission during the past few years, accompanied by Mrs Siemewicz, will spend the next three months in Europe, where the doctor will visit many of the more important tuberculosis clinics and make a special study of the various phases of anti-tuberculosis work.

Dr John Stewart, Dean of the Faculty of Medicine of Dalhousie University, who commanded the Dalhousie Unit during the war, celebrated his eightieth birthday on July 3rd. A host of friends called upon the Dean to wish him many happy returns of the day, and he was the recipient of many congratulatory letters and telegrams from distinguished colleagues in various parts of the world.

It was a source of much delight to the medical profession of Nova Scotia that the annual meeting of the Canadian Medical Association, at Charlottetown, should have been so successful. Bluenose physicians generally extend hearty congratulations to their colleagues of the tight little Island upon having earned through a very ambitious undertaking with such conspicuous success.

The Sutherland Memorial Hospital which replaces the Pictou Memorial Hospital was opened with appropriate ceremonies on June 27th. His Honour, the Lieutenant Governor was present and made a congratulatory address. Dr John Stewart of Halifax, whose earlier years of practice were spent in Pictou, unlocked the doors and declared the hospital open to the public. Among others who spoke was Dr Kenneth A. MacKenzie of Halifax, who claimed Pictou as his birthplace. The hospital is an attractively designed, well planned brick building, and occupies a beautiful site which commands a broad view of Pictou harbour and surrounding country. A very generous contributor to the new hospital is Mr Daniel Sutherland, a highly respected and much beloved citizen of Pictou.

The Refresher Course for Nurses, arranged last year by Dalhousie University, proved so successful that a very general desire was expressed that it should be made an annual event. This year the course was held during the latter part of June, and attracted a large attendance of nurses from each of the Maritime Provinces. Contributing to the program were a number who do not belong to the Dalhousie staff, notably Miss Beard, director of the nursing activities of the Rockefeller Foundation, who gave greatly enjoyed addresses on three days, and otherwise took an active part in the proceedings.

In connection with the summer school now being conducted by the Department of Education, more attention is being given than formerly to the teaching of Public Health. Drs Jost and Chisholm, of the Provincial Department of Health, and Dr C. S. Marshall, Provincial Psychiatrist, are giving instruction which is intended to impress the teachers with the importance of public health work, and to point out to them the opportunity they have of instilling the principles of personal hygiene in the minds of school children.

Word has been received that Mr Harry S. Morton, the son of Dr Charles S. Morton, of Halifax, has passed the second examination for the medical degree of the University of London, and has also passed the primary

Fellowship examination of the Royal College of Surgeons, London

Dr Lewis Hunt, a native of Nova Scotia, who has spent the greater part of his professional career in England, died recently at his home in Richmond. For several years, Dr Hunt was mayor of Richmond. Last

summer he spent several months in Nova Scotia, looking up old friends

Dr D J Hartigan, of New Waterford, has ventured into a field which is rather new for physicians. He and his brother have purchased a coal mining property, with the intention of developing it. W H HATTIE

QUEBEC

Infantile mortality continues to take its toll, though the figures are improving. Returns for last December give an infantile mortality rate for the Dominion of 85 per 1,000 living births, as against 100 per 1,000 in the December previous. Quebec, among the provinces, had the highest infantile mortality rate for last December, namely 112.4 per 1,000, Ontario the lowest, with 65.6. Quebec's rate shows a big improvement, as against 125 in December, 1926. Alberta shows the biggest relative improvement. In December, 1926, the Alberta rate was 113.2, last December it was 68.8.

Following an address on health by Dr A. Lessard, Director of the Provincial Bureau of Health, the county council of Chambly decided to apply for a health unit with a clinic. These health units are established by the provincial authorities, and at the meeting at Longueuil lately it was decided to apply to the Rockefeller Institute for additional assistance. Part of the expense is paid by the county and part by the province, and the county chooses the doctor. This doctor passes his certificate test, and is then eligible for the position of caring for the clinic or health unit. He cannot then be discharged except with the approval of the government. Not only physicians, but nurses are planned for Chambly County. They will instruct the women in their community in the care of infants. The probable centre for the health clinic will be Longueuil. The council plans also the introduction of serums for certain diseases.

In connection with the appointment of the new head of the Provincial Police, it is believed that Dr Wilfrid Derome, medico-legal expert, will be given a new post, that of technical advisor to the Provincial Police and director of scientific research. Dr Balthazard, in Paris, Dr Reiss, in Geneva, and another medico-legal expert in Lyons, are filling such positions, and it is said that a police department which has once had the many advantages of a scientific director should not be without such an officer.

Dr J. E. Belanger, President of the College of Surgeons of the Province of Quebec, has been appointed medical officer of the new Workmen's Compensation Board, which will commence its duties on September 1st.

The construction of an annex to the Civic Hospital of Quebec will in all probability be deferred until next year, as the amount which was tentatively suggested, \$40,000, is insufficient to build anything which will be practical. It is likely that the Civic Hospital item will be dropped from the forthcoming referendum and will be put on the list for next year, in a revised form. The ratepayers will be asked to vote on a larger amount, which will include both the cost of construction and furnishing the annex.

Since the navigation season opened nearly thirty cases have been treated at the Immigration Hospital in Savard Park, Quebec, for scarlatina, measles, diphtheria, and fractures. A new wing is to be added to the present hospital, which will give an additional 180 beds, and at the same time provide quarters for

clinics, sterilization, and x-ray. Tenders are to be called for the construction of the annex, which is expected to cost \$75,000. Work will be pushed in order to have the wing completed for the autumn.

The City of Montreal provided two thirds of the people on whom inquests were held in the Province of Quebec during 1927, according to official statistics. Among these, French Canadians outnumbered all others by 20 per cent. In all, there were 3,227 persons upon whom inquests were held during the year, and their numbers, by nationalities, were as follows: French Canadians 2,329, Canadians of British origin 424, Scotch 68, Irish 125, others 136, Italians 25, Russians 12, Greeks 5, Americans from the United States 13, other nationalities 90. Montreal provided 1,282 French Canadians, 389 English Canadians, 64 Scotch Canadians, 87 Irish Canadians, and 130 other Canadians of British origin. In addition, inquests were conducted in the city of Montreal over 34 Italians, 11 Russians, 3 Greeks, 10 Americans, and 66 other nationalities for a total of 2,066, out of a provincial total of 3,227. Three judicial districts did not hold a single inquest during the year, these being Hull, Richelieu and St. Francis, the latter in the Sherbrooke district.

Montreal's first Anti-diphtheria Week will be ushered in this month. This is being instituted by the Child Welfare Association in order to immunize the 90,000 children of the city, between the ages of one and ten years, against the disease. Dr A. B. Chandler, Medical Director of the Child Welfare Association, stated that four clinics would be operated by the association in different parts of the city. Three inoculations will be given the patients at intervals of two weeks. Each clinic will be operated by two doctors, five nurses, and five voluntary workers. A charge of 50 cents will be made for each child for the full course of three inoculations, the money to go towards the cost of material. The Medical Director remarked that, in view of the saving of \$100,000 to the city in grants that they have made in previous years to the various hospitals for diphtheria purposes, it would be appropriate for the city to pay the 50 cents required from each child for the inoculations.

In a lengthy report on American museums by Dr E. E. Lowe, Director of City Museums and Libraries of Leicester, published recently by the Carnegie United Kingdom Trustees, tribute was paid to the exhibits in the museum at McGill University and the methods of preparation of these exhibits. Special reference was made to the Strathcona Museum in the medical building, which is being rearranged under the direction of E. L. Judah, Curator. It is expected that this will be opened to the public early this autumn. Dr Lowe said in part: "The McGill University of Montreal contains fine medical and other museums which are in the process of steady development, but are at present largely directed towards purely university teaching." In another part of the report, reference was made to the beautiful skeletal preparations, which Dr Lowe said were excellent, due to a large extent to the care taken by the curator.

GEORGE HALL

ONTARIO

At the June examinations for admission to the College of Physicians and Surgeons of Ontario, there wrote successfully 42 from the University of Toronto, 6 from the University of Western Ontario, and 2 from McGill. The actual number of applicants who were writing is not given.

The following details of the final examination at the University of Toronto Faculty of Medicine are given by the secretary of the Medical Faculty —

Number of students in final year who graduated, 100, number who graduated with Honours, 3, number who passed with Honours, 9, Faculty Gold Medal, B Willmsky, D.D.S., First Silver Medal, J W Shier, B.A., Second Silver Medal, E F Brooks, J J Mackenzie Prize in Pathology, B Willmsky, D.D.S., The Chappell Prize in Clinical Medicine, E F Brooks, George Armstrong Peters Prize in Surgery, B Willmsky, D.D.S., Starr Silver Medal, F N Allan, M.D., *cum laude*, The Ellen Mickle Fellowship, B Willmsky, D.D.S., The Charles Mickle Fellowship, Sir Henry Head, F.R.S., M.A., M.D. (Cantab.), M.R.C.P., Lond., M.R.C.S., Eng., F.R.C.P., LL.D., Edin.

The Secretary of the Medical Faculty of Queen's University makes the following announcements in connection with the final year in medicine. The degree of M.D., C.M., was conferred upon 57 gentlemen. No less than 50 obtained hospital appointments in various institutions of Canada and United States. The prizes and awards were as follows —

The David Edward Mundell Scholarship of \$50.00, awarded to the student making the highest aggregate marks in the Surgical Applied Anatomy final examinations of the fifth and sixth years, A. B. Susman, B.A., Kingston, Ont.

Canadian National Committee for Mental Hygiene Scholarship of \$50.00, awarded to the student making the highest number of marks in Psychiatry, G. C. Ferguson, B.A., Bishop's Mills, Ont.

A Prize of \$20.00 in gold, given by Dr James of Mattawa, for the best examination in final year Medicine and Clinical Medicine, Honour to G. C. Ferguson, B.A., Bishop's Mills, Ont., Award to H. W. Justus, Winchester, Ont.

A Prize for the best series of pathological cases, given by Dr James Miller, R. K. Start, Toronto, Ont.

Professor's Prize in Medicine and Clinical Medicine, L. B. Carruthers, B.A., Sarnia, Ont.

Professor's Prize in Surgery and Clinical Surgery, H. W. Justus, Winchester, Ont.

Dr D. T. Smith's Prize in Pharmacology, J. A. Kearns, Quyon, Que.

Medal in Medicine, G. C. Ferguson, B.A., Bishop's Mills, Ont. Medal in Surgery, L. B. Carruthers, B.A., Sarnia, Ont.

N. B. GWY

An anonymous benefactor has undertaken to contribute \$50,000 towards the establishment of a Chair of Preventive Medicine in Queen's University, Kingston, in honour of Dr Arthur Elliott, an alumnus who formerly practised in Belleville.

In considering this gift, the authorities of Queen's hope to obtain annual support from the Ontario Government and other interested bodies which will permit the erection of a building costing in the neighbourhood of \$200,000. This Public Health Building will be a part of the Faculty of Medicine, and the hope is entertained that the Provincial Government will make it the centre for the health activities of the eastern counties of the province.

MANITOBA

Hon. Dr E. W. Montgomery, accompanied by Mr Isaac Pitblado, K.C., Dr M. S. Fraser, and Sergt Rose, R.C.M.P., has returned to Winnipeg after journeying more than six hundred miles in northern Manitoba, chiefly by canoe. The party left The Pas June 10th, and returned to that point on June 28th. The trip took them successively to Reed Lake, Elbow Lake, Cranberry Lake, Lake Athapapaskow, Flin Flon, and Mandu Mines, and back via Cold Lake and Sherritt Gordon mines, up Cold River to Flatrock Lake, down to Brentwood Lake, Nelson House and out to Mile 185. The party then went to the end of steel at mile 356, and being advised that ice conditions did not permit sailing vessels to approach Fort Churchill, to which point it had been their intention to go, they returned southward.

Dr Montgomery reports health conditions among the Indians, miners, prospectors and railway workers to be satisfactory.

A successful meeting of the Brandon and District Medical Society was held at Souris on June 29th. The following program was presented: Dr H. O. MacDiarmid (Brandon), "Acute mastoiditis and its complications", Dr Bruce Chown (Winnipeg), "Pneumonias of infancy and childhood", Dr E. J. Boardman (Winnipeg), "Hypertrophy of the prostate".

The biennial meeting of the Canadian Nurses Association was held at the Fort Garry Hotel July 3rd to 7th, under the presidency of Miss Mabel F. Gray, head of the Department of Nursing, University of British

Columbia. At the evening session of July 3rd, addresses of welcome were given by Miss A. E. Wells, representing the Manitoba Association of Graduate Nurses, Mayor MacLean, Hon. Dr E. W. Montgomery, Dr H. M. Speechly, representing the Manitoba Medical Association, and to these Miss Gray, the acting president, made reply. Prof. R. C. Wallace gave an address on the work of the public health nurse, particularly in outlying districts. The question of affiliation of the Canadian Nurses Association with the Canadian Medical Association was under discussion, as was also the national enrolment of Canadian nurses for emergency service in times of disaster, war, etc. At the evening session of July 5th, addresses were given by Hon. R. A. Hoer, Minister of Education for Manitoba, by Miss Ruth Hallows, Educational Director, College of Nursing, London, Eng., on "Tradition in English Nursing," and by Dr A. T. Mathers on "Mental Hygiene and the Nurse".

The new ten bed hospital at Mile 327 on the Hudson Bay railway is now complete in every detail and patients have been received and cared for in it for the past week. This is a modern steamheated structure, built in bungalow style with a full basement, running water, and electric lights. Dr L. R. Shier is the physician in charge, under Drs Orok and Stephansson of The Pas, the C.N.R. surgeons, and Miss E. K. Cotter is the attending nurse. During the past two years, the hospital at Mile 327 has been housed in cars which have lately been removed to Mile 214, with Dr R. E. Holbrook in

charge Twelve bed tents with wooden floors and walls house the hospital at the Silkox River, Mile 394 Drs C B Stewart and A Ferguson are in charge here Drs Orok and Stephansson also have a gas-car patrol carrying a physician up and down the line once a week, and Dr Shier at Mile 327 has a gas car at his disposal

The report of the city of Winnipeg Health Department for the year ending December 31, 1927, is now available The number of deaths, excluding stillbirths, was 1,650 Assuming the population to be 198,932, this gives a gross death rate of 8.29, the lowest death rate for this city on record The number of deaths in children under one year of age was 273, giving a mortality rate of 61.17 per 1,000 living births, which again is a new low rate When infant welfare was embarked on as part of the civic program the rate was 207 Dr A. J. Douglas, Medical Health Officer, feels that it is possible to get the rate of 61.17 still lower, by continuing the work and broadening the education of the public as to its possibilities

The number of births, excluding stillbirths, was 4,463, giving a birth rate of 22.44 per 1,000 population Stillbirths numbered 200 Of the 273 infants who died during the year 106, or 38.8 per cent, died within the first week of life While infant mortality rates were ranging between 100 and 200 per 1,000 live births, still births were of lesser importance, but now that the infant mortality rate is about 60 and the stillbirth rate is 45, the latter assumes a new prominence, especially when it is considered that out of the 273 infant deaths, 64 occurred within 24 hours after birth and that out of the 200 stillbirths registered in 1927 a large proportion occurred within 24 hours before birth

Births in hospitals and nursing homes during 1927 were 73 per cent of the total In 1912 the percentage was 31.5 Physicians were in attendance in 95.7 per cent of cases and midwives in 43 per cent In 1920

the figures were respectively 89.0 per cent and 11.0 per cent

There were 25 puerperal deaths, giving a puerperal mortality rate of 5.6 per 1,000 live births The rate for residents was 4.5, and for non resident women, who were confined in Winnipeg, the rate was 8.6

Of communicable diseases there were 27 cases of typhoid with 6 deaths, 48 cases of smallpox with no deaths, 542 cases of diphtheria with 34 deaths, 885 cases of scarlet fever with 6 deaths, and 221 cases of tuberculosis of the lungs with 74 deaths Of the small pox cases developing within the city all cases were unvaccinated, save two contacts whose vaccinations were performed some days after exposure Dr Douglas points out that the number of unvaccinated people in the city is too high Diphtheria in 1927 showed increased virulence, with 34 deaths, as against 20 in 1926 A group of cases occurred in which the infection was probably due to association of the diphtheria organism and the streptococcus These cases were characterized by the presence of hemorrhagic sloughing membranes, high temperature, great prostration and rapidly fatal termination

The Registrar of the University of Manitoba has received a cable from the Commissioners for the Exhibition of 1851 to the effect that a Scholarship has been awarded to Douglas Roy McCullagh, B.A., M.Sc., a graduate in arts and science of the University of Manitoba and a former medical student Mr McCullagh, whose father is Rev Dr McCullagh, now of Boissevain was full time demonstrator in biochemistry in 1926-27 under Prof A. T. Cameron, and pursued his work for the M.Sc. degree in biochemistry In 1927 he proceeded to Cambridge, where he has worked under Sir F. G. Hopkins He has published in the *Biochemical Journal* a paper on a pancreatic factor, not yet isolated, controlling muscle metabolism

SASKATCHEWAN

The annual meeting of the Saskatchewan Medical Association will be held at Prince Albert, September 13th and 14th. An excellent program has been arranged. The speakers will be Dr Primrose, Toronto, Dr J. C. Meakins, Montreal, Dr Roscoe Graham, Toronto, Dr F. F. Tisdall, Dr T. C. Boutley, Dr G. Harvey Agnew, of Toronto

An extra mural post graduate tour was conducted in this province from July 7th to 18th. Lectures were given at the following points: Swift Current, Moose Jaw, Weyburn, Regina, Broadview, Melville, Saskatoon, Prince Albert and North Battleford. The lectures were conducted by Dr A. P. Hart of Toronto and Dr H. P. Wright, Montreal, and Dr Wm. A. Gardner, Winnipeg

The following medical men have recently registered in this province and are now practising at the following points: C. J. Houston, M.D., L.M.C.C., Yorkton, Sigga C. Houston, M.D., L.M.C.C., Yorkton, J. B. Legault, M.D., L.M.C.C., Doremy, J. B. Swinden, L.R.C.P., L.R.C.S., Edin., L.F.P.S., Glas., L.M.C.C., Rose Valley, James Robinson, M.D., L.M.C.C., Bienfait, Wm. D. McPhail, M.D., L.M.C.C., Kindersley, R. E. Brown,

M.D., L.M.C.C., Regina, R. S. Conn, M.D., L.M.C.C., Regina, L. M. Fairbairn, M.D., L.M.C.C., Estevan

Dr G. R. Davison, formerly of Wiseton, is now practising at Springwater

Dr Leo Langlois, of Marcelin, is now practising at Prince Albert

Dr D. W. Ganton, who formerly practised at Park side, is now at Henribourg

Dr D. A. McKay, of Radville, has opened an office at Crane Valley

Dr J. M. Barnett, formerly of Verwood, has opened an office at Colgate

Dr F. H. Wheeler of Moose Jaw, is now practising at Neville

Dr N. Bellas, who practised at Saskatoon, has moved to Madison, Wisconsin, U.S.A., where he will do institutional work

ALBERTA

The annual meeting of the Alberta Medical Association will be held at Edmonton on September 18th, 19th, and 20th

The annual meeting of the Alberta Hospitals' Association was held in Calgary on June 25th and 26th, and

was well attended by representatives from many of the hospitals throughout the province

The following officers were elected for the coming year: Honorary President, Dr R. G. Brett, Banff, President, Dr A. H. Baker, Calgary, Vice President, Dr A. E. Archer, Lamont, Secretary, Dr J. A. Montgomery, Edmonton.

The meeting of the Alberta Association of Public Health Officers was held in Calgary during the same period, and some of its sessions took place jointly with those of the Hospitals' Association. Several papers of much interest were read, and proposals made for the betterment of hospital affairs and of health conditions in the province.

Dr A E Archer of Lamont presented a paper on the "Health Inventorium," a name suggested by the American College of Surgeons "as one by which might be organized the facilities of the staff and equipment of the hospital, in such a manner, that it would be feasible to conduct thorough health examinations periodically for any member of the community. Such an individual having these periodic examinations would know what were his health assets and his liabilities, and he would be the better able to plan his mode of living with intelligence and in greater safety. Each standardized hospital should set aside a room in which the family doctor could make his examination and have at hand every possible equipment, laboratory, x rays, etc., as well as provide consultants to determine as accurately as possible the patient's condition."

Dr M B Bow, Deputy Minister of Health, placed before the meeting a proposal "for the establishment of a district health department or unit where several municipalities might be grouped together, and whose medical needs would be under the control of a thorough trained and competent health department, instead of under a medical health officer acting under a small retaining fee." Each unit would consist of twenty-five thousand inhabitants.

The Alberta Association of Public Health Officers elected the following officers: President, Dr T H Whitelaw, Edmonton, Vice President, Dr Duncan Gow, Calgary, Secretary-Treasurer, Dr S Main, Edmonton.

The second of this year's extra mural post graduate tours was held between July 3rd and 16th, and from every point of view was entirely successful. We were fortunate in having a group of clinicians who were able to give instruction of such excellent quality in the special work in which each is engaged. Every lecture and clinic was well attended and followed with great interest. There was more general discussion at these meetings than usual, which gave them an additional value.

Dr G R Pirie and Dr S G Ross, of Toronto University, Dr J G McKay, Superintendent of the British Columbia Mental Asylum, and Dr J W Arbuckle, of Vancouver, comprised the list of visitors. The cities and towns visited were Medicine Hat, Lethbridge, Calgary, Drumheller, Hanna, Red Deer, Stettler, Camrose, Edmonton and Vermilion.

At Calgary, on July 5th, clinics or talks were given at the General Hospital in the morning by Dr J W Arbuckle, on "Eclampsia", by Dr G R Pirie, on "The rheumatic heart in children", by Dr S G Ross, on "Pneumonias of childhood".

In the evening at the Country Club, lectures were given by Dr S G Ross, on "Diarrhoea and vomiting in children", by Dr J G McKay, on "Psychiatry as pertaining to general practice", and by Dr G R Pirie, on "Constipation in Children".

An advisory board to the Department of Health has been named by the Provincial Government. The personnel consists of Dr W A Wilson, President of the College of Physicians and Surgeons of Alberta, who will represent the medical profession, Dr George Johnson, Registrar, representing the College of Physicians and Surgeons, Professor E L Pope, representing the Faculty of Medicine of Alberta University, Dr D Gow representing the Association of Provincial Health Officers, Dr R H Smith, representing the Superintendents of City Hospitals. Representative for the

rural municipal hospitals, C Stevenson, Secretary, Red Deer Municipal Hospital. The Alberta Nurses Association will have a representative, and there will be two lay women and two laymen representatives.

The travelling tonsil clinics still continue to function in this province. From recent reports they are not seeking the assistance of local physicians. In answer to the criticism made during the past year that children were not properly examined prior to tonsillectomy, the government has appointed Dr Heber Jamieson of Edmonton to the staff of the clinic.

There has been considerable agitation in several of the municipal hospital districts that sub-hospitals be established in towns nearby to the municipal hospitals. These municipal hospitals have filled a long felt need in country districts. Moreover, the ratepayers have hospitalization at one dollar a day, yet experience has shown that where the hospital district covers several towns or villages, the physicians in the remaining villages, other than the one in which the hospital is located, are simply emergency men and are unable to make a living. The result has been that in some of the smaller towns the residents are without a physician. Unless sub-hospitals are established, or unless the government permits of smaller taxable areas for the erection of six or eight bed hospitals, the present state of affairs will be aggravated.

Plans for extensive additions to the Royal Alexandra Hospital, Edmonton, were recently passed upon by the Hospital board and forwarded to the City Council with the recommendation that they be adopted and the required funds be raised. The cost of the new wing will be about \$178,000.00, and of the nurses' home \$80,000.00. For some time the accommodation in the hospital has been greatly taxed.

Dr W A Wilson, of Edmonton, President of the Council of the College of Physicians and Surgeons of Alberta, is attending the Canadian Medical Association meeting at Charlottetown, where he will give a review of the new laws recently passed by the Alberta Legislature, affecting the medical profession.

Dr J H. Egbert, of Halkirk, is now practising at Berwyn, in the Peace River District. Dr M. Mates of Kitchissippi has also located at Berwyn.

Dr Wilbur McPhail, until recently associated with Dr Swartzlander of Oyen, is now in practice at Kindersley, Saskatchewan.

Dr W F Carscadden, of Bowden, has taken over the practice of Dr C V Scott, of Innisfail, and has entered into partnership with Dr C A. Wagner of this town. At present Bowden is without a physician.

Dr Arthur Scott, a graduate of Toronto University, has become associated with a group clinic of Drs Macnab and Lincoln of Calgary, as pathologist.

Dr Percy H. Sprague, a graduate of Alberta University in 1927, is now associated with Dr J V Baker of Edmonton, having spent the past year in the Provincial Pathological Laboratory.

Dr T G Michie, of Edmonton, is at present acting as locum tenens at Kimberley, B.C., before entering on post graduate work in the east.

Dr C H McKenzie, recently stationed at Wainwright, has accepted the appointment of physician to the municipality of Ituna, Saskatchewan.

Vitamins Essential

to the Health of the

Mother & Child

FOOD values are no longer decided by Chemical Analysis alone. Growth and development, the maintenance of the defensive powers of the body against the germs of disease, and freedom from Rickets have been demonstrated beyond doubt to be dependent on the food containing those vital qualities known as Vitamins.

Important investigations conducted at the Bio-Chemical Laboratories of the University of Cambridge have demonstrated that the Vitamins so rich in the foods of which Virol is composed are not destroyed in the process of manufacture, but are found in their active state in the preparation as it reaches the public.

More than 3,000 Hospitals, Sanatoria and Infant Welfare Societies are regularly using Virol.

VIROL

VIROL LTD, HANGER LANE, EALING, LONDON, W 5

Sole Importers Bovril Limited, 6201 Park Avenue, Montreal
Sales Agent Harold F Ritchie & Co Ltd., 10 McCaul St., Toronto

Dr James Kenny, formerly of Retlaw, is now practising in Buffalo, N Y

Dr E A Johnson, a recent graduate of Alberta University, is looking after the practice of Dr F F Law, of Tofield, during his absence

Dr Charles B Rich of Manitoba, is now in practice at Kitscotv

Dr L L Cairns of Trochu has moved to Calgary

Dr J R Dean of Elnora has taken over his practice

Dr E McGregor, who has been associated with Dr

R Parsons of Red Deer, has left for Philadelphia. His place will be taken by Dr Ernest Hunt, a graduate of Toronto University 1927, who has completed a year's internship at the Toronto General Hospital. Dr Hunt is the son of Mr W G Hunt, Associate Secretary of the Alberta Medical Association

Dr Terence Agnew, of the 1928 class of Alberta University, has opened an office at Peace River Crossing. Dr W Barr Murray, of the same class, is practising at Irma.

Dr W G Saunders of Sedgewick is now associated with Dr G M Little of Viking. There is a municipal hospital at this point. G E LEAFMOUTH

BRITISH COLUMBIA

The annual meeting of the Fraser Valley Medical Society was held on June 19th, when the following officers were elected for the ensuing year: President, E H McEwen, New Westminster; Vice-President, Bruce Cannon, New Westminster; Secretary, H L Collins, New Westminster; Chairman of Program Committee, W A Robertson, New Westminster.

The Pacific North West Paediatric Society met in Vancouver on June 28th, and the Canadian Association for the Study of Children's Diseases met the following day at the Hotel Georgia. Both meetings were well attended. Among the speakers were Drs H B Cushing and A W Canfield, who are touring British Columbia under the Canadian Medical Association post graduate committee. Other speakers were Drs Geo R Pirie, H P Wright, A P Hart, H Spohn of Vancouver. Golf proved a welcome change from too keen an attendance at lectures.

Dr A S Lamb, Government Inspector of Hospitals and Travelling Medical Health Officer of British Columbia, together with Dr A D Lapp of Tranquillo

Sanatorium are leaving at the end of August from Quebec, to attend the International Tuberculosis Conference in Rome. Some thirty medical men are making the trip under scholarships from the Sun Life Insurance Company. In addition to attending the conference in Rome, the party will attend clinics in England, Scotland, France, and other European countries.

Dr D E H Cleveland has been elected a member of the British Association of Dermatology and Syphilology (Canadian Branch).

Dr W W Chipman has left Vancouver for the east, and will go on to Europe, where he intends doing post graduate work in Vienna and other centres, returning to British Columbia in about three months.

Dr C W Prowd, Radiologist of St Paul's Hospital, and Dr H H McIntosh, of the X Ray Department of the Vancouver General Hospital, have left to attend the International Congress on Radiology at Stockholm.

UNITED STATES

The Inter State Post Graduate Assembly of North America will hold its convention this year at Atlanta, Georgia, from October 15th to 19th. A splendid program has been prepared. The morning of each day is devoted to diagnostic clinics, conducted by some of the most outstanding men in the profession in the United States.

Symposia will be held on malignant diseases, gynecology, diseases of the genito urinary, cardio vascular, respiratory, gastro intestinal and central nervous systems, and on diseases of the liver and gall bladder.

Among the visitors from outside the United States are a number of well known medical men from Great Britain, Northern Ireland, and Canada. These are, G E Waugh, MD, FRCS, London; Charles Macaulay, FRCS, Edinburgh; Sir James Dundas Grant, FRCS, London; Hugh Thursfield, FRCP, London; A Ralph Thompson, FRCP, London; William Ibbotson, FRCS, London; J E R McDonagh, FRCS, London; T P Dunhill, FRCS, London; L S T Burrell, MD, London; L S Dudgeon, FRCP, London; Farquhar Macrae, FRCS, Glasgow; Otto F Leyton, FRCP, London; J Howell Evans, FRCS, London; Archibald Young, FRCS, Glasgow; Donald Core, FRCS,

Manchester, L L Cassidy, FRCSI, Dublin; Sir Farquhar Buzzard, Oxford; F W Marlow, Toronto.

From other countries come, Drs. Edmund L Gros, Paris, France; C Beuttner, Geneva, Switzerland; D J Cranwell, Buenos Aires, Argentina; and Morris Roth, Geneva.

The program, as put forth, is of the highest interest and importance, and the convention will be well worth attending.

The 57th annual meeting of the American Public Health Association is to be held this year in Chicago, Illinois, from October 15th to 19th, with the Hotel Stevens as Association Headquarters. The American Child Health Association and the American Social Hygiene Association are to meet at the same time with this organization. The chairman of the local committee is Louis E Schmidt, MD, and the secretary is Arthur E Gorman.

It should be noted that the annual meeting of the Canadian Public Health Association in Winnipeg will be held on October 12th, 13th and 14th, making it most convenient for those planning to attend the meetings of both associations.

GENERAL

According to a report issued by the Health Organization of the League of Nations, there has been a great decrease in the incidence of small pox in European countries during recent years. The only exception to this general rule is offered by Great Britain, where there has been a steady increase in the number of cases officially reported since 1920. In 1927 there were 14,931 cases in Great Britain, as compared with 6,841 in the rest of Europe. The disease is common only in a mild form, known as alastrim, but this mild form has been notably absent from Continental Europe, with the exception of Switzerland, where between 1921 and 1926 it persisted in epidemic form. In 1927, however, no cases were reported in that country. Despite the large number of cases in Great Britain, the mortality has been very low, no deaths having occurred in Scotland between 1922 and 1927, and only 49 deaths in 1927 in England and Wales. During the period under review the disease was limited largely to the north of England and the Midlands. Of 10,141 cases reported in 1926, 10,070 were reported from Durham (6,645), Yorkshire (1,270), Derbyshire (982), Northumberland (843), Nottinghamshire (191), and Lancashire (139). During the winter of 1927-28 a wider diffusion of infection occurred, 4,711 cases were reported from 38 counties in England and Wales in the first quarter of 1928, but the mortality has been almost negligible. The report states that vaccination within ten years appears to give complete immunity to the disease. Thus in 1926 there was not a single case among children below 12 years of age who had been vaccinated in infancy, whereas there were no fewer than 3,980 cases among children below 12 years of age who had never been vaccinated. That part of the report dealing with Russia shows a remarkable decrease in the number of cases since the war. In 1919 there were 186,755 cases, which gives a rate of 30 for every 10,000 inhabitants, in 1926 there were only 16,547 or 11 to every 10,000 inhabitants, in 1913 there were 4 cases to every 10,000 inhabitants. No case of small pox was reported in Bulgaria, Czechoslovakia, Denmark, Gibraltar, Hungary, Lithuania, Luxembourg, Malta, or Rumania in January or February of this year.

The tenth international medical post graduate course, with special reference to balneology and balneotherapy, will be held at Carlsbad from September 23 to 29, 1928. Clinicians and scientists from the medical faculties of Austria, Bulgaria, Czechoslovakia, Denmark, England, France, Germany, Italy, Norway, Poland, Sweden, Switzerland, and the United States of America will give addresses. England will be represented by Professor Hugh MacLean and Dr George Graham. An invitation

is extended to all medical practitioners. Those who accept will receive a passport visé without charge and a 33 per cent reduction on all state railways in Czechoslovakia. A program of entertainments has been arranged. Full information may be had from Dr Edgar Ganz, secretary of the medical post graduate course, Carlsbad, Czechoslovakia.

It is announced in the January issue of the *British Journal of Anaesthesia* that a prize of £50 is offered in commemoration of the late Dr Sidney Rawson for the best research on inhalation anaesthesia between now and December 1st. In sending the essay a *nom de plume* is to be used, further information may be obtained from the editor of that journal "Ainsdale," Palatine Road, Withington Manchester.

Ten lectures will be given at the Hôpital de la Charité, 47 rue Jacob, Paris, with roentgenologic projections and anatomical specimens, on the subject of diseases of the bronchi. Each lecture will be followed by practical demonstrations by MM. Bordet, Oury, Turpin, Kourilsky, and Benda.

The lectures will take place from October 29th to November 3rd, inclusive.

In the morning practical demonstrations will be made in the wards under the guidance of Professor Sergent.

The afternoon will be devoted to theoretical courses (from 2 30 p.m. to 3 30 p.m., and from 4 p.m. to 5 p.m.)

PROGRAM

Dr F. Bordet, "Lipiodol in the diagnosis of the diseases of the respiratory tract," (two lectures)

Dr Oury, "Bronchial forms of pulmonary tuberculosis,"

Dr Turpin, "Carcinoma of the bronchi," (two lectures)

Dr Kourilsky, "Lung abscess," "Bronchiectasis," (two lectures)

Dr Benda, "Bronchial forms of pulmonary syphilis," (two lectures)

Fees 500 francs (about \$20)

A certificate, signed by the Professor and the Dean of the Faculty of Medicine of Paris, will be given after the course to every doctor who has attended it regularly.

Dr Julius Wagner Jauregg of Vienna, who discovered the malarial treatment of patients with general paresis, has been awarded the Nobel Prize in Medicine for 1927.

Sleep Affected by Orientation (Points of the Compass)—Researches of Féré, Duchatel, Waucollier, and Reichenbach show that the position most favourable for regular and sound sleep is with head to the north, and the worst position is with head to the west. A series of carefully conducted tests of the variation of

blood pressure, of the different constituents of the blood, etc., prove that these are least when the person is lying with head to the north. This may explain the calm and restful sleep many persons enjoy when lying in this position.

Book Reviews

Four Centuries of Medical History in Canada John J. Heagerty, M.D., D.P.H., Department of Health, Ottawa. Two volumes. Vol. 1, xiii and 395 pp., 14 illustrations, vol. 2, vii and 374 pp., 24 illustrations. Price \$12.00. The Macmillan Co. of Canada, Limited, Toronto, 1928.

The publication of these volumes is a distinct event in the history of the medical profession in Canada. As Dr. Heagerty well remarks in his preface, "In no country is the history of medicine so well-preserved as in Canada, in no country is the story so all-absorbing, so replete with striking incident." Hitherto, numerous, but disjointed, portions of this story have appeared in various magazines, in transactions, and formidable archives, and we indeed owe a debt of gratitude to those who have striven to give us some idea of the wealth and value of our historical heritage. Among these we may mention specially D. A. Campbell and W. H. Hattie, in Nova Scotia, M.M. P. G. Roy, E. Z. Massicotte, P. L. N. Beaudry, the Abbé Casgrain, M. J. and Georges Ahern, A. H. David, Sir William Osler, W. H. Drummond, John McCrae, Maud Abbott, H. S. Birkett, M. Charlton, Sir Andrew MacPhail, in Quebec, and William Canniff, A. H. Wright, H. B. Anderson, and Thomas Gibson, in Ontario. Particularly noteworthy are *The History of Medicine in Lower Canada*, by Miss M. Charlton (*Annals of Medical History*, 1923, V, pp. 150 and 263, *ibid.*, 1924, VI, pp. 223 and 312), and *The Medical Profession in Upper Canada*, by Canniff (Briggs, Toronto, 1894). But, interesting and important as these are, they are but partial accounts. Dr. Heagerty's special merit lies in the fact that he has gathered together records, not easily accessible to the general reader, and has made them readily available to the student of medical history.

One has only to open the book to see where Dr. Heagerty's affections lie. With scarcely any preamble he plunges at once into the history of the great epidemics which have devastated Canada from the earliest times,—Mal de terre, small pox, mal de Siam, plague, ship fever, mal de la Baie St.-Paul, leprosy, cholera and influenza. This takes up 212 pages out of a total, in the first volume, of 393, the consideration of Public Health takes up 56, in addition to 50 more in the second volume. This ensures very thorough treatment. The balance of volume two deals with medical schools and hospitals, and there is an appendix on the medical history of Newfoundland.

This topical method of dealing with the subject is due to the desire of the author to create a work of reference for the student of Canadian medicine, rather than to write a story. In pursuance of this design the bibliography and the index are arranged topically also, which makes for ready reference. In consequence, much of the romance of the story is lost. Yet, so much is inherent in the subject that it inevitably crops out and does much to lighten the narrative.

As might be expected, the older settlements in the east receive the greater share of attention. Their recorded history goes back three hundred years and the record is remarkably complete, still the west is not forgotten.

The chapter on the pioneer physicians in the various provinces is good and of the highest interest, as are also the chapters dealing with medical societies and medical journals. The chapter on Medical and Surgical Progress is inadequate, considering the importance of the subject, occupying a scant seven pages. Medical legislation is dealt with in a helpful way. We note that the first medical society in Canada was the Quebec Medical Society, founded in 1826.

The illustrations are well selected but poorly executed. That of the Hôtel Dieu of Montreal is particularly bad. This is unfortunate, as this fault detracts from the appearance of an otherwise very pleasing bit of craftsmanship. A few typographical errors were noted in the first glance over the work, which will, doubtless, be corrected in another edition. In volume one, page 71, the word "hemorrhagic" is spelled "hemorrhagic" three times, on page 6 "Lorraine" should be "Lorraine," on page 225, "St. Corne" should be "St. Come."

It may truthfully be said that Dr. Heagerty has performed a signal service in bringing together so much interesting and valuable material in connection with the many and varied activities of our profession. Only those accustomed to literary work can appreciate the amount of time and industry required to consult the records as the author has done. A valuable feature, also, is that Dr. Heagerty has endeavored to let the various authorities speak for themselves, and quotes many of the more important records verbatim, or translates them literally. The result is an authoritative work, which will be for long what the writer wishes it to be a reliable work of reference. It may well prove the inspiration for others to bring out works on certain aspects of Canadian medical history, perhaps along other lines, but which will add to our store of knowledge on the subject. *Four Centuries of Medical History in Canada* should be in the hands of every medical man in this country.

A. G. NICHOLLS

Die Aeusserere Sekretion der Verdauungsdrüsen. B. P. Babkin, M.D., D.Sc. xiii and 886 pp., 145 illustrations. Second edition. Price (unbound) 63 reichsmarks. Julius Springer, Berlin, 1928.

This book on *The External Secretion of the Digestive Glands* forms volume XV of a series of monographs dealing with the whole range of the physiology of plants and animals, edited by Drs. Gildemeister (Leipzig), Goldschmidt (Berlin), Neuberg (Berlin), Parnas (Lemberg), and Ruhland (Leipzig). The first edition appeared in 1914.

Professor Babkin was for ten years assistant to the renowned Parnas in St. Petersburg, and himself assisted his teacher in the elucidation of many of the important problems connected with the function of digestion which the latter dealt with so helpfully in his epoch-making work of 1898. In this first edition all the work done on the subject in various countries was for the first time brought together.

In this, the second edition, the author has preserved the general plan of the first, giving, where possible the original work and the particular methods of research on which his conclusions are based, but he has also collected and collated the vast literature on the subject that has accumulated between 1914 and 1927. He has more fully elaborated his text, and has added some new chapters, such as, *The Continuous Secretion of the Gastric Juice*, *The Blood-supply of the Pancreas*, *The Secretion of Bile*, *The Function of the Gall-bladder*, and *Some Motor Phenomena of the Alimentary Canal*. The second edition, then, is practically a new book, but yet preserves the spirit of the first.

Professor Babkin brings unusual qualifications to his task. Thoroughly grounded in his subject during his long association with the great Russian physiologist, he became professor in the University of Odessa, after the revolution he was enabled to make his escape to England, and worked in the Physiological Laboratories of University College, London, where he obtained his D.Sc. degree, he came to Canada in 1924 as Professor of Physiology in Dalhousie University, Halifax, and has quite recently been appointed a Research Professor in Physiology at McGill. Well acquainted with English, French, German, as well as his native Russian, he is particularly well fitted to cover the extensive literature of his subject. This he has done well, and, perhaps, for the first time in an important work published under German auspices has justice been done to the research workers in other countries. The scope of the research in this particular can be seen from the fact that out of about 2,600 references more than 900 are to British and American work. Among Canadians remembered are, Archibald, Collip, Drever, Meakins,

1st FIRST!

Mead Johnson and Company studied samples of cod liver oil coming from the site of production, i.e., Labrador, Newfoundland, Nova Scotia, Iceland, Maine, Massachusetts, Japan, British Columbia and Norway, and found that Newfoundland oils were the most potent

Pediatricists noticed a difference in Cod Liver Oil and asked Mead Johnson and Company to make an investigation as to the origin of various cod liver oils

Mead Johnson and Company were

FIRST to place on the market a biologically assayed and standardized cod liver oil

FIRST to own and operate their own factories and rendering stations, thus controlling the oil from the time the fish were caught until it was placed in the bottles for the market

FIRST to place the oil in brown bottles, thus preventing the destructive effects of light

FIRST to use a proper seal to prevent the entrance of air causing oxidation of the oil

FIRST to arrive at standard laboratory methods for testing the oil for Vitamin A and Vitamin D

FIRST and only to test the oil from the livers of each catch of fish in preference to blending a number of batches of oil before testing. In this way batches of oils that do not come up to standard are rejected

FINALLY, Mead Johnson and Company place upon the market, oil of known origin and unquestionable potency

Mead Johnson & Co. of Canada, Ltd

Infant Diet Materials Exclusively

BELLEVILLE, . . . ONTARIO

McLarren and his own pupils Margaret Mackay and H S Morton

The book is divided into seven sections, dealing respectively with the salivary glands, the gastric glands, the pyloric portion of the stomach and the Brunner's glands of the duodenum, the pancreas, the secretion of bile and its discharge into the duodenum, the glands of the small and large intestines, and the motor phenomena of the alimentary canal

Each section is introduced by a brief account of the anatomy of the organs concerned. The operative technique in connection with the various experimental manipulations referred to is given in the necessary detail, with often, explanatory drawings. The various stimuli, the innervation, and the chemical constitution of the various excretions are fully given

While to a large extent dealing with theory and the pure science of the subject, the book is intended at the same time to be practical and of value to the clinician. Hence we find such subjects dealt with as the relationship of the saliva to dental caries, and the application of gastric physiology to the elucidation of surgical problems connected with the stomach

The book has the usual appearance of the German scientific monograph, with clear text and convenient references. As might have been expected, it is well arranged exhaustive, and simply written. No important detail is lacking. In the judgment of the reviewer, Professor Babkin's work is one of great value, the most complete, and the most authoritative on the subject that has yet appeared

A G NICHOLLS

Atlas der Histotopographie gesunder und erkrankter Organe von Dr. Erwin Christeller, Direktor der Pathologisch Anatomischen Abteilung des Städtischen Rudolf Virchow Krankenhauses in Berlin. With 192 directly reproduced coloured prints in 88 plates and 4 text figures. Published by George Thieme, Leipzig, 1927. Bound in linen with gold lettering

In this handsome volume the results of the author's researches into the structural relations of the body tissues in normal and diseased states by his own method of making frozen sections through entire organs for microscopic study and demonstration purposes, are set forth with much technical skill and in a highly instructive context. Its publication marks a new departure in the art of scientific reproduction, in that the negatives for the printers' use in the coloured plates are made directly from stained and mounted frozen sections, without the intervention of photographic prints, and it also represents a distinct advance in the field of tissue diagnosis and pathological research, in that the histological picture of the entire organ so obtained supplies a topographical survey of the interrelations of the disease process along its zone of delimitation or advance that is of the greatest possible value. As the author puts it in his Foreword, we have before us not merely a mass of authentic pathological data for the inspection and information of students, specialists, and research workers, rather it is his intention to show here that, from the employment and extension of technical methods in common use, a real step forward has been made both from the diagnostic and didactic standpoints, and new paths established for the successful investigation of the combined macro and microscopic phenomena of disease. Up to this time this topographical method has been largely neglected. Small pieces of tissue are taken from suspected points and their relation to each other laboriously reconstructed with a necessary element of uncertainty that often leaves room for doubtful conclusions. Frozen sections through the entire organ taken in such a way that its normal contour and relations are preserved, cut sufficiently thin for microscopic study and cleared, stained, and mounted under a coverglass are substituted to great advantage. Neuropathology was the pioneer in this field and the central nervous system has long been studied with the help of serial sections through the entire brain differentiated by

special stains and fixed in celloidin. Never before have such large frozen sections been cut from other organs, and the results, as shown in this Atlas, are highly illuminating

The volume contains some nineteen pages of Introduction, setting forth the advantages of this method, which is used as a routine process by Dr Christeller and is found much cheaper and simpler, as well as yielding much positive histotopographical information that can be contained in no other way, and a minute description of the technique, both of preparing the *Gesamigefrierschnitten* (total frozen sections), and of the reproduction by the printers from negatives, in three colours, prepared direct from the mounted section. This is followed by some 160 pages of the Atlas, in the plates of which the direct colour print of the section (enlarged one-half) is shown side by side with a three colour reproduction of its microscopic appearances made under a low power magnification from the same section, and with a three colour print from another section through a normal organ of the same kind. On the page opposite to the plates full clinical data with descriptions and key to the lettering of the sections are given, so that each represents to the student a true clinico-pathological entity

The advantages of this method are to the author a matter of daily experience. The proportion of correct tissue diagnoses achieved by him by means of these large frozen sections has been far above that obtained from smaller sections, and he insists that no one who has become accustomed to glance over the entire extent of an organ in this way for patchy areas of disease or a border of delimitation would ever consent to relinquish it. Researches have been made in his laboratory with the assistance of these large frozen sections into the subject of hypertrophy of the prostate (200 case), tumours of the urinary bladder, the histotopography of gonorrhoea, the distribution of neolymphoid tissue in the kidney and appendix, the study of cell emboli and tumour metastases. For instruction and demonstration purposes to students these preparations have proved themselves invaluable, combining as they do the macroscopical impression of the complete organ and the pathological changes in it, with the differentiation of tissues by the various colours obtained by contrasting staining methods which are readily employed, the section being first mounted on its glass slide, and fixed in place with a thin coating of celloidin. Such stained sections are used for direct observation in the hand, or as transparencies by transmitted light, in which case they may be mounted on opaque glass enclosed in wooden frame and conveniently hung in a window. Or they may be shown to great advantage to large classes with the projector, by which their histological details are magnified as readily and as satisfactorily as is the case with an ordinary microscopic slide of small size

It is also an extraordinary advantage that these large frozen sections lend themselves so readily to direct colour reproduction for publication without the intervention of a photographic print, and that enlargement in the process of printing secures more and more perfect detail, whereas, in printing from a photograph, enlargement merely brings the structure of the raw material of the paper itself into evidence, and must therefore be avoided

The greatest value of all however lies in the working over of these large sections (which are usually 20 to 30 ruersons thick) by the microscope with increasing powers. The possibility of examining all parts of the organ by the magnification one chooses, makes the combination of macro and microscopic relations conspicuously helpful and enables one to win in this way an entirely new oversight of the field of normal and pathological histology in an easily demonstrable form. The author warns however against any idea that through its portals a 'new Atlantis' is to dawn for this subject, for the reason that the relatively low magnification

Weston's DIGESTIVE

A "whole meal" biscuit endorsed by doctors and dietists

Weston's DIGESTIVE is a real "health biscuit" made from the original old English recipe of the largest selling health biscuit in the world.

It contains, in delicious palatable form, mild laxative qualities especially suited to convalescents. Weston's DIGESTIVE is the only "fancy biscuit" many dyspeptics can eat.

George Weston Limited, Toronto
Makers of "Biscuits as they are made in England"

sera which have been employed in treatment, since they are really antistreptococcic sera

There is a concluding chapter on the virus disease of bacteria themselves, that is the bacteriophage. It is admitted, however, that this view of bacteriophagy is in dispute.

This book is well worth reading. It is evident throughout that most of the views advanced are subject to criticism, but the whole subject is brought into focus, and very full and well arranged bibliographies are provided with each chapter for those who wish to follow it further.

H. E. MACDERVOT

Text-Book of General Bacteriology Edwin O. Jordan, Ph.D. 9th edition, revised. 777 pages, illustrated. Price \$6.00. London and Philadelphia, W. B. Saunders Co.; McAmish & Co., Toronto, 1928.

The ninth edition of the well-known text-book on general bacteriology, by Professor Edwin O. Jordan, Ph.D., Chicago, Ill., has been brought up to date by the inclusion so far as possible of the latest literature. Many important sections have been revised and amplified, and a number of new text figures have also been added.

New material has been added on the rôle of streptococci in the bacteriology of scarlet fever, erysipelas and rheumatic fever. The Dicks' test and prophylactic inoculation against scarlet fever and its close analogy to the longer known Schick test in diphtheria is given due prominence. The section on the bacteriology of water now includes the recent findings and methods embodied in the Sixth Report of the American Committee on Standard Methods. The chapter on Parasitic Protozoa has been entirely re-written but it is regretted that it has not been still further extended to include the parasitic flat and round worms (Phyla, Platyhelminthes and Nematelminthes), as this would obviate the necessity of the student in elementary parasitology (this course often being included with bacteriology), purchasing a separate book on that subject. In addition to the chapters devoted to the individual groups of pathogenic microorganisms are interesting sections on the common bacterial diseases of plants, bacteria in the Arts and Industries, and on bacteria and the nitrogen cycle.

The description of the various microorganisms is extremely lucid, and includes *Brucella abortus* and *Bacterium tularensis*. A small section of the common bacteria found in the mouth and their significance could, with advantage, be added for the benefit of the dental student and practitioner. The rôle of carriers in disease, while dealt with fairly extensively along with the individual organisms, merits, too, a separate chapter. The chapter on immunity is concise but somewhat brief. In dealing with the differential media employed in the isolation of *B. typhosus* from the feces, etc., no mention is made of MacConkey's bile salt neutral red-lactose agar, a medium which is still used in routine work in Great Britain.

The fact that the text-book has reached its ninth edition since 1908 speaks for its popularity and usefulness. It is eminently readable, accurate, sound and generally comprehensive and thoroughly deserves its continued popularity. Suitable for students and practitioners alike and also for reference by the more advanced investigator, it deals with the fundamental principles and methods of laboratory work, and includes bibliographical references to articles of classical and historical interest. The author has, so far as possible, simplified conflicting views so as to give a readable account of the subject in question, and has included references to the fields where investigation is still active or opinions are at variance, and also some giving valuable summaries of important subjects.

RALPH P. SMITH

Nutrition. Walter H. Eddy, Ph.D., Professor of Physiological Chemistry, Teachers' College, Columbia University. 236 pages. Price \$2.50. The Williams & Wilkins Company, Baltimore, 1928.

There is great need for a book on nutrition written for the general public in simple language. Such a need is met reasonably well by Dr. Eddy's small volume. The

quantitative and qualitative food values of the different constituents of a diet are dealt with, the optimum requirements of proteins, fats, and carbohydrates are stated, and the causes of variations in food value of proteins from animal and plant sources are explained. Reasons are given for our dietary requirements of different mineral elements, and there is a good account of acid base equilibrium and its dependence on diet. The necessity for roughage in a diet is emphasized, and the vitamins are dealt with very fully. Alcohol, as a nutrient, is carefully avoided.

The last one hundred pages of the text are devoted to vitamins. Although the author himself states "it is true that the presence of vitamins in the diet is essential to health, but this presence is no more imperative than calories, nutrient quality, digestibility, etc.," and although, since he himself has done much valuable vitamin research, he is naturally led to emphasize this phase of his subject, yet it seems regrettable that inevitably such a preponderance of page material on this one phase of nutrition must unduly stress it for the lay reader, so that thereby the treatment of the whole subject is unbalanced. Much of the experimental vitamin procedure that he has detailed could well have been omitted. In its place a section dealing with the effect of food-preparation on food value is badly required. The very few formulae and equations could well have been eliminated.

In spite of such imperfections, the book will have a real use in conveying to the man in the street and his wife many of the facts regarding the universal occupation of eating that we all should know, especially in these days of "purified" foods. The author's attitude with regard to food advertisements and vitamin advertisements is sound. He endorses McCollum's advice: "The place to get vitamins is in the market, in the grocery store, from the milk man, and from the garden, and not from the drug store." The physician will probably find the book of service in introducing it to patients whose co-operation in dietary measures he wishes to secure.

A. T. CAMERON

Mongolism. Kate Brousseau. Revised by H. G. Brainerd, M.D. 302 pages, 47 illustrations. Price \$4.50. Williams & Wilkins Co., Baltimore, 1928.

The material presented in this work is based upon personal experience with Mongolian imbeciles and other types of defectives, during a period of ten years. The tabulated statistics and the charts were compiled from personal observations as well as from case reports published in medical literature. More than one thousand of these were studied. From this wealth of material the authors have presented, in most excellent form and order, the best single study of this condition.

Following a brief historical review the various theories regarding etiology are thoroughly reviewed. The authors then proceed in order to discuss pathology, diagnosis, prognosis and finally the education and training of these defects. Many excellent photographs illustrating the various physical defects are interspersed throughout the text which lend materially to its value.

This monograph may well be recommended to the research worker, the psychologist and the teacher.

ALAN BROWN

The Ultra violet Rays. Their Action on Internal and Nervous Diseases and Use in Preventing Loss of Colour and Falling of the Hair. Arnold Lorand, M.D. 258 pages. Price \$2.75. F. A. Davis Co., Philadelphia, 1928.

This volume describes the experience of the author in the use of actino therapy in the treatment of a large number of internal diseases of obscure origin and doubtful etiology, ranging from hyperpirosis to canities and alopecia. Rather more than half the book is devoted to the causation and treatment of the latter conditions. In the early chapters Dr. Lorand gives an interesting résumé of heliotherapy, ancient and modern, the character of sun light under differing geographical and climatic conditions, and the varying effects of the elements of the solar spectrum.

The undoubted beneficial effects of ultra-violet radia-

SOMNOL

5 grain tablets — Absolutely non-habit forming

B & L 2502 Colorimeter

with the "Easy to Read Scale"

TRANSLUCENT scales, a reflecting prism and a magnifier provide an excellent means for reading this Bausch & Lomb Colorimeter from the eyepoint position

The verniers, too, are read from this same position. They are graduated to tenths and are easily adjustable by means of clamping heads on the back of the instrument

Because the source of illumination of these scales is the same as that of the colorimeter mirror, a reading can easily be obtained even in a darkened room

This "Easy to Read Scale" is just one of the many features that will give you a convenient and accurate means of colorimetry comparison. Complete details will gladly be furnished at your request

BAUSCH & LOMB

OPTICAL COMPANY

670 St Paul Street

-

Rochester, N.Y.

tion are ascribed by the author to its action upon the endocrine glands and the sympathetic nervous system. In estimating the effect of treatment, Dr Lorand has made no effort to narrow the active agent down to the ultra-violet ray, but has utilized at the same time any other method of treatment which has been thought to be of value, *e.g.*, (p 87), "I have obtained the most striking results in ageing women by the administration of thyroid, ovarian and occasionally pancreatic extracts, in combination with the quartz-light, radio-active mud baths and certain amounts of iodine and arsenic."

As a spa physician Dr Lorand's patients are no doubt chiefly drawn from the well-to-do class of bored neurotics, in whom the psychical value of a new form of treatment will count for much. In the comparatively few cases of definite organic disease which he refers to (*e.g.*, gall-stones) that portion of benefit attributable to the ultra-violet ray is very indefinite indeed.

In his technique Dr Lorand is a trifle vague. "Of course the treatment should not be overdone, the sitting should not last too long, and the source of light should be neither too far or too near," (p 85).

The book will probably achieve greater popularity with the general public than with the medical profession. The language is simple, technical expressions are avoided, even the term alopecia areata is carefully defined and the statements are so general as to leave much to faith.

The publishers have done well. The book is of a convenient size, well printed in large type on good paper, and strongly bound. W T LOCKHART

International Clinics Edited by Henry W Cattell, A M, M D, and others. Vol II, 38th series. Price 3 00 each volume, \$12 00 for set of four. J B Lippincott Co, Montreal, 1928.

This volume marks another semi-centennial stage in the "International Clinics." It is the 150th volume issued since the foundation of the undertaking in 1891. There is an introductory note by Sir Humphry Rolleston recalling the fact that the 100th volume was the occasion of an article by Sir William Osler, in which he spoke of the coming of age of international medicine in America. The present editor, Dr H W Cattell, has been in charge of the "Clinics" for the greater part of the time since 1900, and has been one of the guiding influences of the publication. Dr A McPhedran in a note on Canadian contributions mentions the steady increase since the first article on insulin by Banting in 1923, although there had been a few articles from Canadian authors before that.

Taken all round, this volume is thoroughly well edited and arranged, covering a wide variety of subjects in medicine. H E MACDERMOT

An Introduction to the Technique of Section Cutting Edited by Frances M Ballantyne, M A, Assistant in the Zoology Department, the University of Glasgow. xi and 61 pp, 2 figures. Price three shillings net. E & S Livingstone, Edinburgh, 1928.

In the introduction to this little work Professor J Graham Kerr points out the need for a satisfactory small, elementary book which can be recommended to junior students as providing reliable instruction in the ordinary stock methods of cutting microscopical sections in paraffin and celloidin. The methods described are arranged and elaborated from the notes of the late Mr Peter Jamieson, expert technician in the Department of Zoology of Glasgow, and from those of Professor Kerr.

Care is taken to put forward only the simplest and most essential elements in the technique, but the many small things that make for success are by no means overlooked. Scrupulous attention to the necessary detail is inculcated. The fixative recommended for the beginner

is a saturated watery solution of corrosive sublimate containing five per cent of glacial acetic acid. Dehydration is to be brought about by successive baths of 30, 50, 70, 90, and 100 per cent alcohol. The paraffin recommended is that of the best quality, translucent, and bluish in colour, with a melting point of 52 degrees C. It should give a metallic ring when struck on a wooden table. Simple staining, in bulk and on the slide, is described. After the bare outlines of the paraffin method have been set forth, a complementary chapter is given which contains many additional hints of value, together with certain modifications that may be required for special purposes.

The celloidin method, both for serial and single sections, is described fully, and useful hints in regard to the use of section knives are given.

The book well fulfils its purpose and can thoroughly be recommended for laboratory use to the beginner.

A G NICHOLLS

Local Anæsthesia. Geza de Takats, M D, M S. 221 pages, illustrated. Price \$4 50. London and Philadelphia, W B Saunders Co, Canada, McAnish & Co, Toronto, 1928.

This book clearly and concisely covers the whole field of local anæsthesia as we know it to-day, and as such deserves a place in the library as a text for the beginner and a reference for the initiated. Its sequence is good. It is brief and to the point and free from the monotonous preamble so frequently found at the beginning of medical books. The print is clear and easily read, and the illustrations are excellent.

The only criticism, if such it be, seems the too free use of adrenalin as a binder for the novocaine in subcutaneous and deep injections. Many of us feel that the untoward reactions, which some times occur in the use of local anæsthesia, are often, if not always, due to the patient's idiosyncrasy to adrenalin rather than the toxicity of the novocaine. A J STEWART

A Treatise on Diseases of the Hair and Scalp. S Dana Hubbard, M D. 500 pages. Illustrated with 77 engravings and 4 coloured plates. Price \$5 50. Lea & Febiger, Philadelphia, 1928.

This treatise is a resumé of the known facts with regard to physiological and pathological conditions of the human scalp, and, as the author says, it has been compiled so as to give a practical digest of the subject.

In addition to chapters on anatomy, physiology, and clinical conditions that may be encountered in the hair and scalp, there are special chapters dealing with cosmetics, dressing and curling the hair and public regulations of beauty culture, matters that concern the barber shop or beauty shop and are not of direct medical or dermatological interest. The subject matter is essentially practical and special attention is directed to treatment.

A HAPPY COMBINATION

The aim in scientific medication has always been to combine the highest degree of efficiency with the lowest degree of risk—for it is almost a truism in medicine that any drug powerful enough to do good may also if incorrectly used do harm. Thanks to the research work that is so intensively carried on by our best pharmaceutical manufacturers the element of danger is being reduced without impairing the element of efficiency and this applies to both chemical and biological products—iodine mercury the salicylates antitoxins antigens etc.

One of the most striking examples of this class of work is the separation of the virulence of rabid brain tissue from its antigenic activity. By the method of Dr Cumming (dialysis) a Rabies Vaccine is offered by Parke Davis & Co Winkerville Ont which cannot possibly infect the patient with rabies but which is claimed to be much more efficient as a prophylactic after the bite of a mad dog than the original Pasteur vaccine.

EPIDIDYMITIS

Epididymitis in the opinion of A L Wolbarst M D

'Gonococcal Infection in the Male' is by far the most frequent complication of gonorrhea and of paramount importance sociologically because of its remote consequences.

Acute epididymitis is usually accompanied by inflammation of the vas deferens of the affected side or by an inflammation of the corresponding testis or by both. There is tense swelling of the epididymis and not rarely associated inflammation with serous exudation in the tunica vaginalis. Occasionally the pain in the vas is quite severe and radiates upward and backward through the inguinal ring to the seminal vesicles which share in the inflammatory process. This referred pain may lead to the erroneous diagnosis of acute appendicitis.

Acute epididymitis should be treated by rest (physical and sexual) and elevation of the scrotum and the constant application of heat. Diathermy according to Dr C Otis Rich ('Diathermy in Acute Epididymitis' *Illinois Medical Journal*) yields results which vary 'from the most spectacular improvement to frank disappointment.' Heat in the form of antiphlogistine dressings usually gives marked relief in these painful conditions. Thermotherapy with the aid of this endermic, bacteriostatic agent is essentially decongestive and relaxant removing thereby the tension on the inflamed cord at the same time preventing blood stasis in the affected urea. Being plastic adhesive non irritating and thermogenetic the physician will find in antiphlogistine a distinctly convenient method for prolonged thermotherapy with complete absence of tissue irritation or toxic action. (Denver Chemical Co New York)

(Denver Chemical Co New York)

Two types of constipation

and the proper treatment for each

THE necessity for distinguishing between two types of constipation is urged by a well-known writer in a leading medical journal

The first or "so-called atonic type of constipation," states this authority, "may be attributed to a lazy colon to weakness of the voluntary muscles concerned"

The second or spastic type is held by the author to be due above all to an unstable nervous system, either congenital or "acquired through the unceasing combat with the demands of modern civilization"

In both types, of course, improper diet—foods of too little bulk and too low in vitamin content—and lack of exercise are important causal factors

In treating either of these two types of constipation, the author declares, "Drugs are rarely indicated, except in cases of acute illness or when the constipation is the result of such conditions as senility, anemia, cancer, diabetes, kidney disease or insanity"

Instead, more natural corrective measures are to be recommended. For example "A sufficient amount of water is always required—hot water, especially on rising, for the spastic patient, cold for the atonic

In all cases a moderate amount of exercise, particularly of the abdominal muscles, is required" — together of course with a proper

selection of the protective foods—fruits, fresh green vegetables and—most important of all in the opinion of the majority of doctors—fresh yeast

Fleischmann's Yeast is carefully grown under ideal conditions, from yeast strains of the purest culture. Rich in vitamin B, it possesses an anti-putrefactive power that renders it of unusual value in cases of intestinal toxemia. It softens the fecal masses, too, increasing their bulk and moisture content. Through its tonic action on the bowel muscles it definitely stimulates peristalsis.

In digestive disorders and the common skin affections its results are no less pronounced. It increases the flow of gastric juice and induces a marked hyperleucocytosis. Its mild systemic effect recommends it in below par conditions.

PHYSICIANS usually suggest three cakes of Fleischmann's Yeast daily, one before each meal or between meals plain or in water or any other way the patient prefers. *For stubborn constipation it is most effective when suspended in hot water (not scalding), a cake before each meal and at bedtime*

A copy of the latest brochure on yeast therapy, containing a bibliography of articles on the subject, will gladly be mailed upon request. The Fleischmann Company, Dept. 471, 208 Simcoe Street, Toronto, Ont.

Announcing

a New Improved Carbon Arc Lamp

BRITESUN DUO-ARC AUTOMATIC

THIS lamp has new and exclusive features which really make it two carbon arc lamps in one. It has two sets of carbons each set with a separate resistance so that the sets can be operated together or independently.

Snapping the four way switch to the first position starts the set on the left in action, snapping it to the second position puts both sets in operation, in the third position, the set on the right is left burning, in the fourth position, both sets are cut off.

Thus it is possible to get any degree of intensity or any part of the spectrum desired without changing carbons. Infra Red carbons may be placed on one side and Ultra Violet on the other permitting the use of either merely through turning the switch. Or four Ultra Violet carbons may be employed to obtain

double the intensity of the average single arc lamp.

This handsome new lamp, while massive in appearance, is mounted on double-set ball bearing casters making it easily portable. The heavy aluminum reflector is highly polished outside with satin finish inside. The head is easily raised or lowered by a counter-balance arrangement on a nickel hexagon upright.

The entire stand and right can be swung around in a circle, through swivel mechanism, without moving the base.

Carbons have a maximum burning period 31½ hours without changing.

The Britesun Duo-Arc Automatic is handsome, convenient, efficient, and reasonable in price. Full information on request, without obligation.

A Foot Examination may reveal the origin of many ills

*Flexible Shoes are
Capable Corrective Agents*

FOR reasons of policy—if nothing else—the modern physician bears constantly in mind the possibility or probability of existing foot trouble. A surprising number of complex symptoms, variously diagnosed as rheumatism, neuritis, sciatica, pains in the abdomen, the back, etc., are frequently caused by misalignments in the foot structure.

Careful physicians examine the feet, and, when ever necessary, take proper measures to correct any existing trouble. The result is more satisfied patients, less faulty diagnoses and increased reputation, for being a thorough and efficient doctor.

Because of its natural, corrective lasts and helpful support, physicians who have made a study of requirements find the flexible Cantilever Shoe a valuable aid in treating such cases.

Cantilever Shoe

(For Women, Men and Children)

These physicians prefer the Cantilever Shoe because it, alone, combines the following features:

- 1 A last shaped like the normal foot
- 2 A flexible shank (arch) which permits free circulation and strengthening exercises of the arch muscles
- 3 A heel of sufficient base for correct posture and scientifically wedged to direct the weight onto the outer border of the foot
- 4 A slender 'waist' which grasps the foot just back of the ball giving normal support to the instep, and a flexible shank which forms a natural 'Cantilever' spring to absorb the shocks of walking
- 5 Excellent quality and smart style to please the eye consequently, the Cantilever Shoe is allowed to do its work with no mental opposition on the wearer's part.

So many medical men have been impressed by these healthful features that a large number of prominent physicians and their families are wearing Cantilever Shoes continually.

THE MEDICAL AUDIT ASSOCIATION

44 VICTORIA STREET, TORONTO

THE CANADIAN MEDICAL PROTECTIVE ASSOCIATION

Founded in 1901, at the Winnipeg meeting of the Canadian Medical Association, and incorporated by Act of Dominion Parliament, February, 1913. Affiliated with the Canadian Medical Association 1924.

Objects

To defend its members against cases of alleged malpractice, and to encourage honourable practice in the daily work of the medical profession. The annual fee is three dollars per calendar year, half rates after July first.

Qualifications for membership

All members in good standing of the Canadian and various Provincial Medical Associations, may be enrolled upon signing the application form and paying the annual fee. All other regularly qualified practitioners must have their application countersigned by two members of our Association. Blank application forms and other literature upon request.

Address all correspondence to the Secretary-Treasurer

Who Would Trade in a Snook?

An extract from a report by a Victor representative, following his call on one of the largest clinic in the country

"I just returned from ——— clinic and find the Snook Transformer that was installed in 1924 grinding out as strongly as ever. On Tuesday they ran two hundred chests, which called for four hundred exposures

"I want to call your special attention to their 100 M. A. Coolidge Tube which they have been using on their Snook machine not quite a month. Radiographs of 3695 patients, or a total of 7308 exposures, were made with this tube and it is still going strong"

To give such consistent service a machine must be correct in design.

A FEW months ago a Victor representative called on a physician who for several years had been using a Snook machine in his completely equipped X-ray laboratory

This physician, being successful both professionally and financially, had come to the conclusion that inasmuch as he turns in his auto every other year or so, to get the advantages of the latest model, it was high time that he turned in his Snook for the same reason. The idea was soon dispelled, however, when the doctor was informed that even though he had purchased his Snook ten years ago, it would be equal to all demands of present-day technic in radiographic diagnosis

The Snook stands alone in this respect, and users in all parts of the world attest to the economy of their original purchase, also to the advantages in having a machine with which they can produce radiographic results second to none, and continue to do so consistently

There is only one SNOOK!

Why McKesson Apparatus gives a Better ETHYLENE NARCOSIS

ETHYLENE like wet nitrous oxid tends to freeze when administered by the continuous flow method. Every user knows this to be true. Freezing disturbs the proportions and the depth of anesthesia varies as a result, often requiring the addition of ether to overcome unevenness of anesthesia, which might not be necessary if freezing were prevented.

The McKesson intermittent flow principle prevents freezing by fracturing the ice at the valve nozzle at each breath. This is a clinical advantage that is recognized by all McKesson users who have used continuous flow appliances.

Probably more ethylene is being administered through McKesson appliances than all others.

HIGH BLOOD PRESSURE PATIENTS SUFFER MORE DURING HOT WEATHER

Hot, dry days induce rapid perspiration, increasing hemal viscosity, capillary stasis follows, then vascular congestion and so a vicious circle.

The nearer the primary cause in applying treatment the better will be the results. The degree of viscosity of the blood varies in the same individuals.

Blood pressure is high on dry days and low on damp days. During dry weather plenty of water should be drunk.

PULVOIDS NATRICO

(High Tension, Brunton Thrush)

is the product that thousands of physicians are using satisfactorily and successfully in the symptomatic treatment of High Blood Pressure, pending the determination the cause and if possible correction.

In Pulvoid form insuring disintegration of friable aggs and especially coated to travel stomach intact and disintegrate in intestines, thus avoiding gastric disturbance.

1 to 3 Pulvoids q i d, or as directed by the physician.

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal-i-to-sis) N N L

(L Halitus—Breath Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose, or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth, hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis

The volatile antiseptic constituents of Listerine—thyme, eucalyptus, gaultheria and mentha combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents, hence, Listerine is often corrective of these disorders associated with the endo development of gases and acid eructations. A large tablespoon of Listerine in a wine glass of hot water will afford immediate relief

What ?

*Milk with a bacterial count
of less than 100 per c.c.?*

Dryco is the milk of which this enviable record is true! The bacterial count is consistently below 100 per c.c. and these are harmless spore formers! This information is valuable to every physician who wishes to avoid the incidence of milk-borne infections which are especially prevalent among infants during the warm weather.

{ It is significant as to the merit of Dryco, that it has
for years been prescribed by physicians all over the
world They know that it can be depended upon for
good results and is of special value in difficult feed-
ing cases }

Dialyzed ANTIRABIC VACCINE

RABIES VACCINE (CUMMING) consists of rabic brain tissue that has been dialyzed against running water until the infectivity of the virus is completely destroyed. The vaccine is incapable of causing rabies when injected into a susceptible animal, either hypodermically or intracranially. The intracranial test is applied to every lot manufactured.

The relative purity of the product is such that its use in human practice involves a minimum risk of toxic effect of any kind.

Moreover, with the highest attainable degree of safety in administration, Rabies Vaccine (Cumming) combines an exceptional protective efficiency. Given soon enough, and in connection with the proper treatment of the wound, its record in the 20,000 or more cases in which it has been used is one of practically uniform success.

Rabies Vaccine (Cumming) is sent on telegraphic order to any point in the Dominion, day or night. Orders may be addressed to our laboratories at Walkerville or to the following branches: Montreal, P. Q., 1101 St. Alexander St., or Winnipeg, Man., Keeyaden Bldg., Portage Ave., East.

IMPORTANT to PHYSICIANS SPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponds Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician but lacerations leucorrhoea gonorrhoea prolapse post-operative and post confinement treatment, and uterine hemorrhage are some of the conditions in which Ponds Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponds Tampons.

Ponds Tampons are packed in six tampons to a box and are made in the following medication

Full information and samples will be gladly furnished to physicians addressing us on their own stationery

A—Ichthol Compound, Glycerin and Boro-Glyceride 50% Ichthol 25% Resublimed Iodine 14% Carbolic Acid (absolute Phenol) 5%, Powdered Hydrastis 1% B—Ichthol 10% Glycerin and Boro-Glyceride 50% C—Protargol and Ichthol (Each 2%) Glycerin and Boro-Glyceride 50% D—Opium, Belladonna and Hyoscyamus Glycerin and Boro-Glyceride 50% Powdered Opium 2 grains Extract of Belladonna 1 grain Extract of Hyoscyamus 2 grains. CERVICITIS and ENDOCERVICITIS

do not cause acute pain but by reason of extension of the infection by way of the lymphatics into the parametrium there is often considerable sensation of weight and bearing down in the pelvis. In these conditions it is surprising what relief can be given by the insertion of the Antiphlogistine tampon, which, on account of its marked hygroscopic property, induces an abundant serous transudation.

Antiphlogistine

with its 45% c p glycerin, is ideally adapted for the vaginal tampon, combining as it does, the much needed mechanical support with the *prolonged* glycerin action. Leading obstetricians and gynecologists generally concede its practical value in all those cases where prompt depletion is a paramount consideration.

Antiphlogistine is antiseptic, non-irritating and by virtue of its thermogenetic potency may be relied upon to maintain moist heat longer than any similar preparation now available to the medical profession.

Analysis

No matter where you buy "Canada Dry" the flavor is always uniform

THIS fine old ginger ale tastes the same it has the same allure and subtlety whether you buy it in Halifax or Victoria. The reason is because we take very definite steps to have it so

Not only do we buy the finest quality of ingredients but we insist on the grade being always the same. Then, those ingredients are blended in an exact proportion under laboratory methods. A check-up is made, hourly, throughout the day to determine whether or not the proportions are varying from the fixed standard.

The water we use is of a uniform degree of softness. The purity of the beverage is a matter of hourly examination. The finest quality of Jamaica ginger which is used in "Canada Dry" must come up, always, to our specifications.

As a result you have a delightful beverage always the same with a uniform degree of carbonation achieved by a secret method. Consequently, the sparkle of "Canada Dry" is retained long after the bottle is opened.

"Canada Dry" does not contain capsicum (red pepper). It does not bite the tongue nor leave an unpleasant after-effect. It is a mild, mellow carbonated beverage and one always refreshing and stimulating to patients. It is often prescribed by physicians and leading hospitals serve it.

"CANADA DRY"

Made in Canada by J. J. McLaughlin, Limited, Toronto and Edmonton,
Caledonia Springs Corporation Limited, Montreal
In U.S.A., Canada Dry Ginger Ale, Incorporated, New York

Your Patients voted Kellogg's ALL-BRAN 100% effective

NEARLY seven thousand people, scattered throughout the country, recently gave us their experience with Kellogg's ALL-BRAN. To 98% of this number ALL-BRAN brought complete and permanent relief from constipation. 68% of these people had previously tried and found part-bran products comparatively ineffective.

A remarkable verdict from an impartial jury! ALL-BRAN affords prompt relief to sufferers from constipation. And more than that—prevents its recurrence.

Kellogg's ALL-BRAN supports the aims of the modern medical profession. An appetizing health cereal that supplements the diet. When eaten regularly with milk or cream, with fruits added, with other cereals, or in cooking, ALL-BRAN supplies the bulk necessary to proper elimination of the intestinal tract.

Made by Kellogg in London, Ontario. Sold by all grocers. Served everywhere. In the red-and-green package.

An Egyptian Procession and Ceremony

Whenever the tissue building function of diet is of paramount importance in the treatment of disease and where at the same time there is impairment of function or other obstacle to normal nutrition, "Ovaltine" affords a wealth of nitrogenous and other vital food elements for rapidly rebuilding the wasted tissue and restoring the lowered capacity for the absorption of nourishment

For these reasons "Ovaltine" has a world-wide medical endorsement for its use in the dietotherapeutic treatment of Convalescence, Malnutrition, Phthisis and other wasting diseases, or wherever tissue repair has to be carried out under conditions of difficult alimentation. It is a valuable prescription also in insomnia and diseases of the nervous system

A Misconception

appears to exist in the minds of some members of the Medical Profession in regard to the composition of the 'Allenburys' Foods Nos 1 and 2

*THESE FOODS DO NOT
CONTAIN STARCH*

A New Publication

"The 'Allenburys' Foods in Infant Feeding" has just been issued to all physicians and surgeons on our mailing list. This booklet contains a concise description of the 'Allenburys' Foods and gives full details of their composition and uses.

*If you have not received the booklet, or have mislaid it,
we shall be glad of the opportunity of sending you a copy*

'ALLENBURY'S' Milk Food No. 1 for Infants

is not an ordinary 'dried milk.' When mixed ready for use as directed, it yields a 'humanised' milk having the following approximate composition:

	Per Cent
FAT - - -	3.03
PROTEIN - -	1.7
LACTOSE - -	7.3
MALTO-DEXTRIN	3.3

STARCH IS ABSENT

The addition of malto-dextrin during the process of manufacture protects the fat emulsion and effects in the infant's stomach a fine flocculation of the casein—resembling that of human milk. The daily use of accessory foods such as orange juice and cod-liver oil is an integral part of the 'Allenburys' System of Infant Feeding.

Intestinal Toxemia in Summer

AGAROL is the original mineral oil — agar agar emulsion with phenolphthalein and has these special advantages

Perfectly homogenized and stable pleasant taste without artificial flavoring freedom from sugar alkalies and alcohol no contraindications no oil leakage no griping or pain no nausea or gastric disturbances no habit forming

The increased loss of water from the body without adequate compensation for the loss, the depressing influence of heat without change in diet or daily activity, all tend toward constipation and its deleterious consequences of intestinal toxemia. Many of the headaches complained of by those not directly exposed to the sun rays, are probably of intestinal origin.

With intestinal stasis comes a general debility. The heat gets the blame, but the condition of the intestines may be directly responsible.

The administration of Agarol at the first sign of gastrointestinal discomfort will generally prevent graver consequences by gently reinforcing peristaltic action and maintaining a clean intestinal tract.

OUTSTANDING APPROVED SPECIALTIES

	COMPOSITION	INDICATIONS	DOSES
OVARIAN EXTRACT CHOAY (Compressed Tablets and Ampoules)	Total extract of selected fresh glands dried under high vacuum at 0° and equal to fresh tissues	Menstrual Troubles Puberty Pregnancy and Menopause Troubles Ovarian Deficiency Pruritus etc	4 to 6 tablets of 0.10 ctg daily or 1 ampoule every other day
MUTHANOL (Box of 10 ampoules) (Box of 10 suppositories)	Radiferous hydroxyde of Bismuth in suspension in oil for intramuscular injections	Syphilis Bismutho-Therapy Syphilis in all its forms and stages and also nervous syphilis	One 2 c.c. ampoule every second or third day in series of 10. Same for suppositories
PANBILINE (Pills and Liquid)	Hepatic and Biliary Extracts — Associated with Boldo Extracts Podophyllin and Glycerine	Constipation Intestinal Auto-intoxication Choleraemia Gastro-enteritis Hepaticcholeic Dyspepsia Jaundice etc Arterio-sclerosis	2 to 12 pills a day at the beginning of meals or 2 to 12 teaspoonfuls of liquid
PEPTALMINE (Sugared Pills and Granulated)	Peptones of meat and fish with extracts of eggs and milk — also with magnesia.	Urticaria Strophulus Prurigo Eczema Digestive Troubles Migraines Diarrhea	Two tablets one hour before meals or two teaspoonfuls of granule one hour before meals Children half dose
PITUITARY EXTRACT CHOAY (Compressed Tablets and Ampoules)	Extract of Posterior Lobe of ox pituitary gland obtained in drying under high vacuum at freezing point the fresh organs	Obstetrics Hæmoptysis Uterine Hæmorrhage Gynecological Affections Peristalsis etc	4 to 6 tablets of 0.05 ctg a day or in subcutaneous or intramuscular injections
TRICALCINE (Powder Tablets, Wafers and Granulated)	Assimilable Calcium Salts Also associated with Adrenaline Fluor and Metharsinate	Scientific Rational Treatment of Pulmonary Osseous Renal and Lymphatic Tuberculosis Rickets Scrofulosis Pregnancy-lactation	A measure of powder or one tablet or wafer at each meal Children half dose

LECLERC CATGUTS

Treated in a unique way, right at the slaughter house and as to obtain exactly the proper degree of suppleness and uniform resistance.

Preserved in 90° alcohol they are scrupulously aseptic and need not be boiled.

Samples and literature gladly supplied in any quantities by the exclusive Canadian Representatives

GRAY'S GLYCERINE TONIC COMP.

Formula Dr. John P. Gray

CONSTITUENTS

Glycerine
Sherry Wine
Gentian
Taraxacum
Phosphoric Acid
Carminatives

DOSES —Adults Two teaspoonfuls to a table-spoonful in a little water before meals, t.i.d (or after meals when preferred).

Coughs, Colds, Bronchitis, Teaspoonful every two hours, clear

Children —One-half to one teaspoonful

INDICATIONS

Malnutrition
Anaemia
Neurasthenia
Melancholia
Atonic Indigestion
Catarrhal Conditions
General Malaise

Gray's Glycerine Tonic Compound has proven the ideal Tonic at all seasons of the year for the sufferer from Chronic Organic Disease—Malnutrition, or debilitated conditions generally.

a simple and logical way, perfectly justified from the chemical point of view as well as from the physiological one. Of these four great categories, three refer to organic principles: glucids, lipids, protids, as we are to call them now, according to the international agreement (instead of carbohydrates, fatty matters, lipoids and proteic substances), the fourth refers to mineral substances, that is to say, all the substances free from carbon, or holding carbon in the entirely oxydized form of carbonic anhydride or carbonate.

Indeed, when you study the varied tissues of living beings, so varied as regards their histological structure, their origin, their active or passive part, you discover that there are among them very considerable differences. Some are rich in glucids, and especially in certain glucids, insoluble in the usual reagents, resisting the biochemical actions, such as those that form the supporting apparatus of the plant. Others contain a considerable quantity of mineral insoluble matter, like the bony tissue of the vertebrate animals. Still others are remarkable for the abundance of lipids, which, in certain regions of the nervous system, for instance, represent even 80 per cent of the dry matter, and a still greater proportion in the adipose tissue, which is a tissue of protection and reserve. Others are richer in proteins, like certain glandular tissues of animals, or young seedlings of plants. Finally, still others are exceptionally rich in water, they constitute in that case real "liquid tissues," as blood, for instance.

In each of these tissues, together with the predominant substance, all other sorts of chemical compounds coexist. But, if we leave this superficial way of considering entirely different substances, and come to examine more closely and individually the various tissues, instead of an impression of diversity and infinite variety we have a very intense impression of persistence in composition and stability in the chemical constitution of living matter. Let us now get acquainted with that impression by means of a few examples.

Among the constituents of the organisms, let us choose two groups: that of the *lipids* and that of the *protids*. As those two groups include extremely numerous and varied substances we must be more precise as regards them.

For the lipids, we shall consider, as a whole,

all the bodies, chemically rather different, contained in the ethero-alcoholic extract of animal tissues. I say *animal* tissues, intentionally, so as to leave aside all that concerns plants, because we should otherwise risk wandering too far afield. We shall afterwards examine those things, which, in that intricate group of the lipids, are the most accessible to precise analytical determinations: *fatty acids, cholesterol, phosphorus*.

As regards proteids, we shall localize our attention on the *nucleo-proteids*, those fundamental phosphorus constituents of the cell nucleus, so remarkable for their chemical constitution and whose influence upon the growth, the division and the nutrition of cells, can never be over-estimated.

Let us then consider the total lipid content of the tissues. We find, first, that there is a certain quantity of lipids in all the tissues. None of them are entirely lacking in them. They are fundamental constituents of the cell. We then find (and it is the real object we are concerned with) that the proportion of lipids in a given tissue is of a certain constancy.

If we consider one single animal species, and in that species, individuals placed in as nearly identical physiological conditions as possible, we shall find numbers, not the same of course, but showing only slight oscillations about those averages. There is more to say. If we consider beings belonging to different species, not too far apart in the zoological classification, we find for their homologous organs, contents in total lipids which are not very different. A given histological type of cell element has a certain constancy in its content of total lipids. This constancy, of course, is far from being absolute. When experiment gives too widely divergent numbers it proves that we must take into account, amongst other things, the notion of the physiological state, we ought also to distinguish in the general term of lipids, the real protoplasmic lipids from the reserve lipids. But, let us leave those details aside, though they are very important, and come to the more easily measurable constituents of those lipids. We already mentioned them: total fatty acids, cholesterol, lipidic phosphorus.

Let us thus make a series of quantitative measurements on those three categories of substances which are the most representative of the

group, and for which we now have very precise methods of estimation. Let us examine, with A. Mayer and G. Schaeffer, the analysis of various organs of animals belonging to different species: dog, rabbit, frog, pigeon, etc. This is what their experiments tell us:

CHOLESTEROL

1—For one given species, the dog for instance, each organ has a definite amount of cholesterol.

2—For the different organs, their contents in cholesterol are sufficiently distinct one from the other to constitute real chemical characteristics of these organs. For instance, the lung holds 2 grm. of cholesterol for 100 grm. of dry matter, the testicle 1.8, the kidney 1.2, the liver 0.7, the heart 0.4, the muscle 0.3. These figures are averages around which the real experimental figures group themselves. The individual divergences, though perceptible, are not very important. They are, at the utmost, 5 per cent for the lung, 6 per cent for the testicle, 10 per cent for the kidney. They may be more considerable and reach 20 per cent, and sometimes even more, for muscle.

3—Among different species, the content in cholesterol for homologous organs is of the same order of magnitude. For instance, you find

In the liver of the dog

0.7 grm. of cholesterol for 100 grm. of dry matter

In the liver of the rabbit

0.8 grm. of cholesterol for 100 grm. of dry matter

In the liver of the guinea pig

0.6 grm. of cholesterol for 100 grm. of dry matter

In the liver of the toad

0.8 grm. of cholesterol for 100 grm. of dry matter

One finds also, it is true, figures that differ much from these. For instance:

In the liver of the pigeon

1.2 grm. for 100 grm. of dry matter

In the liver of the frog

1.1 grm. for 100 grm. of dry matter

In the liver of the adder

1.3 grm. for 100 grm. of dry matter

When these discrepancies in figures occur, they are like a characteristic of species; a similar discrepancy then occurs for the other organs, and thus the classification of the latter by their content in cholesterol remains the same in the different species. Accordingly, in the researches of the French physiologists, A. Mayer and G. Schaeffer, from whose work we

borrow these data, we find the following order generally observed: lung, kidney, liver, muscle, decreasing in richness or cholesterol. One is entitled to say that the content of a tissue in cholesterol is for that tissue a real "constant," provided that one does not give the word "constant" a meaning as strict as in mathematical language.

THE FATTY ACIDS

Let us now turn to the fatty acids. For these acids, experiment proves that there is no really characteristic amount for each organ; the content in fatty acids of the liver, the kidney, the lung, the pancreas, the muscle, the heart, may be of the same order of magnitude; one finds, for instance, for the dog, uniformly 11 per cent or about that in each of the above-mentioned organs. The content of the organs in fatty acids, on the contrary, varies in a large proportion, according to the species, and thus the average content in fatty acids for all of the tissues constitutes a real characteristic of species. Lastly, the physiological circumstances, such as the kind of food, the sexual activity, etc., can have an appreciable influence. This is especially evident in birds, batrachians, and fishes, much more than among the mammals.

LIPIDIC PHOSPHORUS

We now come to "lipidic phosphorus," that is to say, that fraction of organic phosphorus one finds as lecithin, or a substance of similar constitution. Here is what the experiments of A. Mayer and G. Schaeffer, and our own, say about that question:

1—The amount of lipidic phosphorus in the organs, expressed in percentage of the dry matter, is, for a given organ of a given species, almost constant.

2—For a given species, the amounts of lipidic phosphorus are, in the various organs, very perceptibly different.

3—For different species, the amount of lipidic phosphorus in homologous organs is of the same order of magnitude. Some organs are very rich in lipidic phosphorus; in the spinal marrow of mammals one estimates about 15 per cent, in the brain about 1 per cent, in the suprarenal and in the hypophysis up to 0.8 per cent.

Other organs are very poor in that form of phosphorus. The muscle is typical, having a content of about 0.2 per cent. The spleen and the thymus are also poor in lipidic phosphorus. Others still have contents of lipidic phosphorus ranging in an intermediate zone, between 0.4 and 0.6 per cent, such are the liver, the kidney, the pancreas, the lung, and the heart. These numbers are calculated for 100 parts of dry matter. But if one calculates the quantities of lipidic phosphorus for the fresh matter in its normal state of hydration, the content in lipidic phosphorus appears as a very characteristic amount in the organs. The organs we have grouped in the third category acquire more individual indices in lipidic phosphorus —

0.10 for the lung

0.13 for the kidney

0.15 for the liver, etc

One might say that these indices could be used to define the tissues.

The facts I have just recalled in a very condensed summary were acquired about fifteen years ago, from a series of researches made by the two French physiologists I have already quoted, A. Mayer and G. Schaeffer. Some time later, I was able myself, with a few of my collaborators (Miles Gloc, Rousseau, Ciémieu, M. Allane) to gather on the same subject, and in quite an incidental way, a fair number of experimental data which, on the whole, agree with those published by our predecessors.

We have recently analyzed, with Mlle Ciémieu, not isolated organs, but whole animals, chosen somewhat at random among the main divisions of the animal kingdom: a coelenterate like *Agartia parasitica*, a worm of the class Chaetopoda like *Nereis versicolor*, etc; a little fish like *Cypin*, and a small mammal like the mouse. We found for their total content in lipidic phosphorus numbers hardly differing one from the other, and several about 200 mgm per 100 gm. of dry matter. The differences between the extreme numbers were certainly not of the order of magnitude one might have expected from the complete diversity of the organisms that had been considered. This is a phenomenon which must be something more than a fact of pure chance, the proof of a certain similitude of composition of all the living matter in that respect.

Now, let us turn to what the analysis of organs shows us about the lipids upon the whole. Mayer and Schaeffer synthesized their thought and expressed the results of their experiments when they spoke of a "lipocytic constant" of tissues and of the existence of "lipocytic indices," among which the "cholesterol index" and the "lipidic phosphorus index" are the most evident. They went still farther. Calculating the ratios between quantities of fatty acids and cholesterol, they noticed that these quantities are for each sort of tissue in a precise constant ratio, and that these ratios vary with each tissue. They were thus enabled to speak of a "lipocytic coefficient" for tissues. For a dog, this ratio is 2.2 in the muscle, 6.8 in the liver, 10.5 in the kidney, 20 in the lung, etc. Thus, the idea that was the starting point of this lecture is justified in one respect. Let us now try to justify a second point. I have already told you we would choose therefor the study of the nucleic compounds.

NUCLEIC COMPOUNDS

Having succeeded in establishing, together with M. Allane, a method, simple in its principle, minute in its application, for the quantitative determination of the fraction of phosphorus which is in the shape of nucleoproteids, or nucleic phosphorus, as we say for short, we wondered whether there was for each tissue of each living species a content in nucleic phosphorus characteristic of each of them, and of a constancy sufficient to constitute a true index. We wondered whether there was an "index of nucleic phosphorus", as there is one of cholesterol and of lipidic phosphorus.

It is hardly necessary to emphasize the importance we were entitled to give to such an index. That nucleic phosphorus is the phosphorus of the essential constituents of the nucleus of the cell. Its value may represent a mode of expression of the nuclear mass, a mass for which numerical expressions are entirely lacking, or are liable to serious objections. This is what we found. For a stated animal, the values of nucleic phosphorus are extremely different for the various organs.

Here are the values we established for the organs of a horse (18 months) —

Organs	Nucleic P in mgm. per 100 grm.	
	Fresh matter	Dry matter
Thymus	249	1,296
Pancreas	141.5	643
Spleen	92.3	390
Suprarenal	63.7	253
Liver	55.6	204
Testicle	47.8	356
Lung	37.2	204
Thyroid	36.9	139
Kidney	33.6	169
Heart	12.8	61
Brain	12.3	75
Muscle	6.1	25
Spinal marrow	6.1	20

The differences between these organs, from the point of view of their content in nucleic phosphorus, are of an order of magnitude such that the numbers which express the rate of nucleic phosphorus constitute real characteristics of these organs, indeed they are real indices. But, to be entitled to speak of indices, the same numbers must be found with sufficient regularity among the various individuals of each species. This is precisely what our experiments verify. Nevertheless, certain differences in the physiological state must not interfere. In that respect, I should like to give two typical examples, one of variation, the other, on the contrary, of stability, for the value of the indices of nucleic phosphorus.

First, the example of variation.

I shall take it in what happens at the beginning of life. A mammal that is just born has a certain total content of nucleic phosphorus, then, as it gradually grows, this content gets smaller and smaller, remains low for a time, then rises again, and rests after a while at a level which remains the normal one for a long time. It is, we may notice, exactly the reverse of the change observed with respect to lipidic phosphorus. Thus at the beginning of life, there are variations of a certain amplitude. We observed them very closely in the rat, with M. Allaire and Mlle. Rousscau.

And now the example of stability.

I shall take it in the researches, undertaken with the same collaborators, on the influence of deficiency of a vitamin, the lipo-soluble vitamin A, upon the chemical composition of animals. While a theoretical idea, which it is not the time to develop here, led us to suppose that this deficiency might cause a sensible fall of the nucleic phosphorus, experiment proved to us that it does not bring the loss of equilibrium of the organism in its content in nucleic

phosphorus. If there is a small diminution because of that deficiency, that diminution is unimportant (in the case of a mouse), and experiments made upon rats, which will soon be published, reduce to nothing the idea that there may be such a diminution. This is, I must say, one of the finest examples I have ever seen of the constancy of composition of living matter in thoroughly different physiological states, since one of them is accompanied with serious health disturbances followed by rapid death, while the other favours a normal growth and evolution.

The amounts of nucleic phosphorus characterize not only the various organs of a stated species, with different species one finds for homologous organs, numbers which are not the same, of course, but which oscillate between very narrow limits. We have analyzed, in recent years, the organs of a fair number of animals. The impression left by careful study is that each organ is characterized by a certain content in nucleic phosphorus. The spleen is rich in nucleic phosphorus, with an index of 300 to 400 (that is to say 300 to 400 mgm of nucleic phosphorus for 100 grm of dry spleen), the liver is not so rich, with an index of about 200, the kidney comes next, with an index of about 150, the brain is poor, with an index of about 70, the heart also, with an index of 55, and the muscle still poorer, with an index of 30. Of course, I am simplifying the facts and am not giving you the details of variations around these average numbers, variations whose causes can be discerned in many a circumstance.

Yet, this is not all. If the study of the quantitative ratios between the constituents of the cellular lipids gives us interesting views on the question, in the same way that of the quantitative ratios between the various phosphorus compounds of cells brings us to some remarks capable of strengthening the notion of cellular chemical equilibria.

In the course of the researches made during the last few years, we have determined the quantitative ratios existing between the different forms of phosphorus and the total phosphorus, and between the different forms of phosphorus themselves, in the organs of various animal species under various physiological circumstances. The ratios offering the greatest interest are the following —

but physical signs give little help in framing the individual prognosis which the patient seeks. This can only be obtained by a careful estimate of the functional efficiency of the organ concerned. In the case of the heart this resolves itself into an estimation of the efficiency of the ventricular muscle, and many means have been devised to this end. Some of these are based upon the reaction of the heart, or of the blood pressure to muscular exertion, others upon certain abnormalities demonstrable in the electrocardiogram. None of these are altogether reliable, and their findings are frequently belied by the subsequent history of the patient. The only test upon which reliance can be placed is the clinical test of the response of the patient to ordinary muscular exertion, *i.e.*, the manner in which he is able to perform his usual daily activities as indicated by the symptoms and sensations to which their performance gives rise. A patient whose myocardium is becoming impaired will recognize a limitation of a definite kind in his capacity for effort long before examination will reveal anything amiss. This method has the further advantage that it is individual, the patient being compared with his own previous normal. The so-called "exercise tolerance" tests have the disadvantage that they lack the essential factor of control. The patient is tested against a standard to which his relation in the days of his normal health is unknown. No reaction which a patient shows in response to muscular exertion can ever be regarded as unimportant, but the real question is, how the reaction at the time of examination compares with a similar reaction in health. In the case of the clinical test, the patient can supply this information with great accuracy.

Much ingenuity has been exercised in the classification of murmurs, especially systolic murmurs, and various conclusions have been based upon these classifications. Thus, systolic murmurs have been divided into those which follow the first sound, those which replace it, and those which occur concurrently with it. Again, they have been classified as blowing, rough or musical according to their quality. Whatever descriptive or diagnostic value such classification may possess, it is entirely inadequate as a means of prognostic assessment. The only factor which is of any importance for this purpose is the capacity of the ventricular

muscle to maintain an adequate circulation. No consistent relation between this capacity and any of the variations which the murmur may show has ever been demonstrated.

Mackenzie classified cardiac murmurs into three groups—the physiological, the functional, and the organic. This classification was introduced as a reaction against the then current view that all murmurs were necessarily of serious import.

The physiological murmur occurs in conditions of perfect health, in which the heart responds normally to every demand made upon it. If from accident or other cause death occurs, the heart shows no abnormality on post mortem examination. Postural systolic murmurs and respiratory murmurs belong to this group.

Functional murmurs are not associated with any organic change in the valve. They usually occur in association with a degree of dilatation of the heart, and are presumably due to relaxation of the mitral ring. They are accompanied with some limitation of the response to effort. Physiological and functional murmurs are always systolic in time. Functional diastolic murmurs have been described, but their occurrence is so rare as to be negligible.

Organic murmurs are associated with secondary changes in the valve, generally of a fibrotic or degenerative kind. The distinction between a functional and an organic murmur is not always possible. In doubtful cases, the history is of the highest importance. A rough or musical quality is perhaps more common in organic murmurs. The importance of an organic murmur is that it indicates that the valve is, or has been, the seat of disease, and raises the question as to whether other and more vital parts of the heart may not have been invaded also. To assess the value of any murmur, it must be considered from two points of view, *viz.*, the condition of the orifice, and the condition of the myocardium.

APPLICATION

Diastolic Murmurs—Diastolic murmurs are nearly always organic in origin, and indicate lesions of valves which embarrass the heart and tend to the production of heart failure. A murmur occurring during diastole means that one of two conditions is present, either mitral stenosis or aortic regurgitation.

Murmurs of mitral stenosis The earliest

sign of mitral stenosis is the occurrence of a short murmur immediately preceding the first sound. At first this murmur is variable, but soon becomes persistent. Occasionally, the first indication of the condition is to be found in a reduplication of the second sound. As the stenosis advances a short diastolic murmur is added, which gradually increases in length as the contraction of the valve orifice proceeds, until it occupies the whole of the diastolic pause. Should fibrillation of the auricle supervene, the presystolic element of the murmur disappears, leaving only the diastolic murmur. In cases where the onset of the presystolic murmur has been observed a fair idea of the progress of the condition can be obtained by observing the rate at which these changes occur. If the case is seen at a later stage, a history can often be obtained of an attack of rheumatic fever which presumably set up the valve mischief, and the rate of progress assessed in a similar manner. The stenosis being due to cicatricial contraction, the presystolic murmur is never heard during the initial illness, but follows it after a considerable interval of time. Exact evidence of the rate at which the murmurs of mitral stenosis develop is scanty, but from a small series of cases in which this condition has been observed to follow rheumatic fever, a period of two to five years elapsed between the attack and the appearance of the presystolic murmur.

In one case of rheumatic endocarditis, in which the heart was examined at four day intervals over a period of nearly two years, the first appearance of the murmur of endocarditis was noted on the ninth day of the illness (January 12, 1922). An aortic regurgitant murmur was noted on February 7, 1923. A reduplication of the second sound at the apex suggestive of mitral stenosis appeared July 27, 1923. Death occurred from erysipelas and septic pneumonia November 1, 1923, no presystolic murmur having developed up to that time. Post mortem examination showed the typical appearance of old-standing endocarditis: narrowing of the mitral orifice, the cusps of the valve being thickened, fibrous, shrunken, and fused with one another at the adjacent margins. The aortic valve was incompetent, the cusps being thickened at their margins and slightly shrivelled.

The presence of a presystolic murmur is in itself a useful starting point for assessing the progress of the condition. Thus, mitral stenosis in young people, accompanied by presystolic and diastolic murmurs, is a very grave condition, whereas in a middle-aged patient, with a history of rheumatic fever in childhood, and only a presystolic murmur present, the rate of stenosis is obviously slow and may even be stationary. In cases which are progressive there are invariably factors present other than the valve change. Rheumatic infection affects all the tissues of the heart and usually produces a degree of impairment of the ventricular muscle. It is upon this factor that the prognosis in the main depends. Evidence of affection of the conducting system—or genetic system, as Mackenzie more correctly called it,—is to be found in the presence of the mid-diastolic murmur. This murmur is separated from both the first and second sounds. Mackenzie demonstrated that it coincided in time with the auricular systole, its occurrence in mid-diastole being due to the fact that the systole of the auricle was separated by a pause from that of the ventricle. The presence of a mid-diastolic murmur, therefore, is evidence not only of the presence of mitral stenosis, but also of a degree of heart-block. There are thus three factors of importance in the assessment of the murmurs of mitral stenosis: (1) the nature of the murmur present, as indicating the condition of the orifice, (2) the rapidity with which the sequence of murmurs is developing, and (3) the capacity of the heart muscle to carry on an efficient circulation, in spite of the obstruction caused by the valvular defect. If fibrillation has occurred, an additional embarrassment is thrown on the ventricular muscle, and in these conditions the prognosis must be based on the third factor, and upon a consideration of the response to treatment. Patients with mitral lesions rarely die in their first attack of heart-failure, however severe it may be, and no adequate prognosis in such cases is possible until the response to treatment has been carefully observed. A considerable proportion of the subjects of mitral stenosis do not die from heart-failure at all—according to Cabot about one-half—but from some intercurrent affection, or from malignant endocarditis.

Murmurs of aortic regurgitation Aortic regurgitation is, as a rule, a very serious condition, though this is not invariably the case. Many elderly people showing the characteristic murmurs of aortic regurgitation lead healthy and even strenuous lives, while others showing identical murmurs pass rapidly into a condition of extreme heart-failure. No valid prognosis can thus be based upon the mere presence of a regurgitant murmur. Nor does the amount of regurgitation appear to be a factor of any particular significance. Even if it were, the possibility of gauging the extent of the regurgitation clinically is an exceedingly doubtful one. The loudness of the diastolic murmur, its length, the presence or absence of the second sound, have been suggested as possible indications of the extent of the regurgitation. The difference between the systolic and diastolic arterial pressure, i.e., the pulse pressure, has been utilized for the same purpose. The main difficulty with such indications is that they are not always consistent in the same patient. Thus, a long diastolic murmur, suggestive of a large leak, may be associated with a moderate pulse-pressure. Apart from the fact that there is no reliable method by which the amount of regurgitation can be estimated clinically, post-mortem evidence gives no support to the view that the extent of the damage to the valve necessarily corresponds with the degree of heart-failure observed during life.

The condition of the pulse, though of little help as an index of the degree of regurgitation, is, nevertheless, a factor of considerable prognostic importance. As a rule, when the systolic pressure is very high and the diastolic pressure very low (190-60), other evidence of heart-failure is present. A moderate difference between the systolic and diastolic pressures (180-90) is quite consistent with an efficient heart while in some cases, the difference is equal to the normal. In these last instances the pulse has little of a collapsing character, though, as Vaquez points out, the abrupt rise of pressure with each pulse beat is apt to convey to the finger an impression of a collapsing quality. When aortic regurgitation is arterial in origin, the diastolic pressure may be consistently high. The pulse condition, therefore, must be considered in conjunction with

the other symptoms present. Among these other symptoms the size of the heart is an important guide. In the cases who lead vigorous lives, free from any suggestion of heart failure, the left ventricle is never more than slightly hypertrophied, the murmurs being dependent upon changes which are, in the main, limited to the valves. In more serious conditions, all degrees of hypertrophy may be present.

The most important prognostic factor in this, as in all other cardiac conditions, is the state of the ventricular muscle, as shown by the response of the patient to ordinary effort. Contrary to what obtains in mitral disease, the heart failure of aortic regurgitation is less susceptible to treatment, and recovery is less frequent and less pronounced than in heart failure resulting from any other condition. Even when heart failure is extreme in mitral stenosis with auricular fibrillation, a good recovery may often occur, but in aortic disease with auricular fibrillation the heart failure is usually steadily progressive, and it is seldom possible to check its progress.

Systolic Murmurs—The assessment of systolic murmurs is conducted on entirely the same principle as has been indicated in dealing with diastolic murmurs. Systolic murmurs, however, present certain difficulties of their own, owing largely to the frequency with which they are functional or physiological in origin. In the case of a systolic murmur arising in the course of an acute affection, the distinction between a functional and organic murmur may be very difficult, and, particularly in the case of rheumatic fever, the gravest issues may depend upon its proper interpretation.

Aortic stenosis In the case of a systolic murmur discovered on ordinary examination, the important point to define is whether or not it is associated with signs indicating that the ventricle is being hampered in its work. The murmur of aortic stenosis is a case in point. A systolic murmur at the base of the heart is in the majority of instances functional or physiological in origin, and is not associated with any evidence of inefficiency of the ventricular muscle. If the aortic orifice is narrowed, the response to effort will be limited and the left ventricle enlarged. A pulse tracing may show the anacrotic pulse sometimes associated with this condition.

Aortic stenosis occurring by itself is an exceedingly rare condition

Mitral incompetence Mitral incompetence by itself probably never constitutes a serious embarrassment to the heart. The recent work of Cabot would appear to indicate that mitral regurgitation is the rarest of all valvular affections, and indeed may be said hardly to exist at all as a pathological entity. How far it exists as a clinical entity is perhaps another proposition, for there does not seem to be any certain means of estimating after death what the competence of the valve may have been during life. While pathological evidence of organic mitral insufficiency may be scanty, functional mitral regurgitation due to relaxation of the mitral ring may be of more frequent occurrence. The question is, however, of little practical importance, for in estimating the significance of systolic murmurs at the mitral valve it makes little difference whether or not regurgitation is present, provided that the heart muscle shows no signs of inefficiency.

A systolic murmur discovered accidentally in an individual who is otherwise in perfect health, and who shows no limitation in his capacity for effort, may be completely disregarded. If it occurs in association with signs indicating a limitation of response to muscular effort, especially if the limitation be that of breathlessness or pain in the chest, the prognosis should be based upon these signs, and not on the murmur, the presence or absence of which does not affect the issue to any degree.

Systolic murmurs arising in the course of acute illness In the course of acute illness a systolic murmur is prone to develop, especially in young subjects, and is frequently associated with a degree of dilatation of the heart. The murmur in the majority of these cases is functional in origin, and usually disappears when convalescence is established. A functional murmur arising in such circumstances is unaccompanied by any signs of deterioration in the patient's general condition. The course of the illness is unaffected, the rate of the pulse remains unaltered, and the patient progresses normally towards convalescence. Coombs lays stress on the fact that the organic murmur is audible in all areas and that the heart is not as a rule enlarged. If a murmur is caused by a lesion which embarrasses the heart in its

work, the chamber affected will alter in form, either by dilating or by becoming hypertrophied. The absence, then, of any alteration in the size of the heart is evidence that there is little embarrassment. The presence of the general characteristics of organic murmurs, such as postural variation, etc., are important confirmatory signs. The distinction between functional and endocardial murmurs is often impossible during the acute phase of an illness. It is necessary as a rule to suspend judgment until the subsidence of the acute attack, when the points of distinction become more evident. This is particularly so in the case of rheumatic fever. In this condition, as in other acute affections, a functional systolic murmur is frequently present. On the other hand, the liability of the heart to rheumatic infection suggests a possible endocardial origin for any murmur which may develop. It is obviously of the highest importance that these two conditions should be clearly differentiated. There is no one criterion which is applicable to all cases. Each must be judged on its own merits, but there are certain general considerations which help towards a correct decision.

The mode of onset of the murmur, and the conditions associated with its development, provide the most reliable indications for this purpose. The murmur of endocarditis usually begins with a blurring of the first sound in the mitral area, and is associated with persistent rapidity of the pulse and a decline, or at least a want of improvement, in the condition of the patient. The blurred first sound soon gives place to a definite murmur and is associated, as a rule, with perceptible dilatation of the heart. Dilatation of the heart may occur in conjunction with a murmur which is purely functional, but these two signs, plus persistent rapidity of the pulse and want of improvement in the general condition, are highly suggestive of the onset of endocarditis. Should rheumatic nodules be present, the diagnosis is practically certain. Endocarditis, which is more prone to occur in young subjects, generally makes its appearance during the first fortnight of rheumatic fever. The murmur itself may not appear for a considerable time, and the heart should be carefully watched for its occurrence until well after the joint symptoms have subsided.

AORTIC INSUFFICIENCY DUE TO RUPTURE BY STRAIN OF A NORMAL AORTIC VALVE*

BY C P HOWARD, B A, M D, C M,

Montreal

IN a hospital experience of twenty-five years I had never seen a case of aortic insufficiency due to rupture of an aortic valve and, therefore, considered the following case report worth recording.

After a brief outline of the case, I shall discuss the incidence of this comparatively rare accident, classify the cases, and then discuss at some length the pathogenesis, pathology and symptomatology of the group.

CASE REPORT

H B, aet 33 chauffeur admitted to the Montreal General Hospital on November 6, 1924, complaining of pain over the heart, palpitation, shortness of breath, cough and swelling of the feet.

Family History—Negative, except that the father died at 53 from "heart disease."

Personal History—The patient denied rheumatic fever, chorea and syphilis. He had been married one year, his wife had had one full term child and no miscarriages. He smoked to excess and used alcohol moderately. He had enjoyed perfect health previously.

Present Illness began on October 6, 1924, when one cold morning, after cranking his car for two minutes, he was suddenly seized with a sharp pain in the left upper chest and especially in the epigastrium, but with no radiation to the arm, he immediately became short of breath and began to cough. He remained at work for some hours, when he stopped on account of the pain in the epigastrium and dyspnea. Subsequently he noted a "thrill" in the left upper chest. He remained in bed two weeks and then returned to work, but was forced to give up again on November 1, 1924 as his symptoms had become very acute. The pain then radiated down the left arm and even to the left leg. He became very orthopneic and vomited constantly. Oedema of the feet also appeared.

Physical examination revealed a large, stout, French Canadian male, in great respiratory distress. The colour of the face was sallow, but cyanosis of the lips, ears and finger tips was present. The thorax was very large. There was impairment of the note at both bases with suppression of the breath sounds and the presence of many moist râles. Heart. There was slight bulging of the præcordium and a widespread heaving impulse visible over the entire left chest, the point of maximum intensity of which was in the fifth interspace, 12 cm. from the midsternum. On palpation over the left base, a very intense vibratory thrill could be felt, perceptible throughout the entire cardiac cycle, but with definite systolic and diastolic intensification. The relative cardiac dullness began in the second interspace and was much increased to the right (5 cm.), but more particularly to the left (15 cm.) of the midsternal line. On auscultation, the heart sounds were replaced by murmurs, whose maximum intensity

was at the third and fourth left interspaces close to the sternum. The systolic murmur was rough and vibratory and filled the entire systolic period, completely obliterating the first sound, though very widely distributed it was of maximum intensity in the second right interspace. The diastolic murmur was of higher pitch, shorter and more musical, and, though propagated to the apex and into the vessels of the neck, was of maximum intensity over the third left interspace close to the sternum. No second sound could be heard. The pulse was of the typical water hammer character, and was rapid, with a palpable vibratory thrill. The sphygmomanometer revealed a systolic blood pressure of 130 mm., and a diastolic that varied from 40 to zero. There was a marked pulsation of the carotid, brachial and femoral arteries, as well as a definite capillary pulse. The electrocardiogram showed an inversion of the "T wave" in all leads. Fluoroscopic examination revealed an enormous heart with no aneurysm. The liver was enlarged and tender. While there was no ascites there was oedema of the legs. In the urine there was a constant albuminuria, but no cylindruria. The blood count was normal, (75 per cent hemoglobin, red blood cells 5,080,000), except for an occasional leucocytosis, (7,500 to 11,000). Two blood Wassermann tests were negative.

The diagnosis favoured was, either a congenital heart lesion with cardiac decompensation, or an acquired aortic insufficiency with the sudden onset of cardiac decompensation due to strain, though the possibility of a rupture of an aortic cusp was suggested by my resident physician, Dr E S Mills, and was seriously considered.

The course was practically a downhill one, in spite of short periods of apparent improvement from the bed rest and digitalis. However, the cardiac distress, dyspnea and oedema increased, and there developed, first, signs of infarction of both lungs, and finally a thrombosis of the posterior tibial vein. Death occurred on January 1st, from progressive cardiac decompensation, practically twelve weeks after the severe muscular effort.

Post mortem—There were, in addition to marked oedema of the lower extremities, dense adhesions about the right lung, with an old tuberculous cavity in the right apex and a scar of the left apex, recent infarcts in the right lower as well as in the left upper and left lower lobes, acute fibrinous pleurisy over the infarcted areas. The common attachment of the anterior and medial (left posterior) cusps of the aortic valve was torn away from the aortic wall, due to a transverse tear in the intima, five eighths of an inch in length, allowing the cusps to become very lax, (see photographs). The mitral valve showed slight thickening. There was a fairly extensive sclerosis in the sinus of Valsalva, and a still earlier process in the root and arch of the aorta as well as the descending aorta. The heart weighed 640 grm., and showed marked hypertrophy with dilatation of the left ventricle and great dilatation of the right. The liver, spleen and kidneys revealed marked passive congestion. Microscopically, the aortic cusp was normal. The vasa vasorum of the aorta showed no evidence of syphilis.

INCIDENCE

Rupture of the healthy mitral and tricuspid valves due to injury from external causes has been known to pathologists since the time of Marat and Corvisart,¹ but the earliest recorded case of rupture of the aortic valve is one by Plenderleath²³ in the *London Medical Gazette* of 1820. Since then some hundred odd cases have appeared in the world's medical literature

A prolonged search through various *referate*, as well as the *Index Medicus*, the *Surgeon-General's Catalogue*, and the *Quarterly Cumulative Index*, reveals a surprising silence on the subject in many of the text-books of medicine and even in the monographs on heart disease. However, as the writer has learnt to expect, Osler² in his *Principles and Practice of Medicine* mentions rupture as a very rare cause for aortic insufficiency, and some of the older writers, such as C. J. B. Williams³ (1839), Thomas Peacock⁴ (1873), Dacosta⁵ (1874), Hilton Fagge⁶ (1877), G. W. Balfour⁷ (1898), Stern⁸ (1900) and Kuelbs⁹ (1909), also describe it in more or less detail. In the medical journals and theses, Quain,³³ Peacock,⁴⁴ Duroziez,⁶⁸ Barié,⁷⁰ Dreyfus⁸⁶ and Dufour,⁸⁷ have published cases of their own and collected all available reports from the literature. Dreyfus was able to find only forty-six cases up to the year 1896. The writer set himself the thankless task of combing the literature from 1830 to 1925 inclusive and succeeded in finding but 112 cases, all of which were not proven, however. The writer's case makes 113.

Cases of so-called "traumatic endocarditis" without valve rupture (Alvarenga,¹⁰ Gerhardt,¹¹ Mayr,¹² Riedinger,¹³ Leyden,¹⁴ Duems,¹⁵ Rumpf,¹⁶ Dieckman¹⁷) have been excluded and, of course, cases of proven ulcerative endocarditis (Williams,¹⁸ Packard,¹⁹ Peacock,²⁰ Salter,²¹ Orlebar,²² Rosenberg,²³ Byrom Bramwell²⁴), as this paper is concerned only with rupture of a healthy or diseased aortic valve from muscular effort or trauma.

CLASSIFICATION

There are two main groups to be considered first, those due to muscular effort or *strain*, and, second, those due to *traumatism*. A third, small, group consists of cases in which the exciting factor is not stated.

The first group comprises sixty cases of which only thirty were proved by autopsy (Plenderleath²³, Henderson,²⁷ Corrigan²⁸ (case 2), Latham-Bence-Jones,³² Quain³³ (case 1), Quain-Jones,³⁴ Peacock³⁷ (case 1), Peacock⁴¹ (case 2), Meschede,⁴⁷ Foster⁴⁸ (case 1), Simpson,⁵² Williams,⁵³ Foster⁵⁷ (case 4), Pepper,⁵⁸ Burney-Yco⁵⁹ (case 1), Frew-Finlayson,⁶⁵ Greenhow,⁶⁶ Lindman,⁶⁷ Lewis,⁷⁷ Leyden⁷⁸ (case 1), Fraentzel,⁷⁹ Tretzel,⁸¹ Hektoen,⁸² Leyden⁸³ (case 2),

Jamieson,⁸⁰ Broadbent,¹⁰⁰ Heller,¹¹⁴ Anderson¹¹⁰ (case 2), Hoffmann¹²⁹ (case 4), Howard¹³⁷) The other thirty cases, though clinically probable cannot be considered as proven in the absence of a post-mortem record in twenty-nine (Aran,³¹ Quain,³⁵ (case 3), Rawson,³⁶ Markham³⁹ (endocarditis?), O'Neil,⁴⁰ Peacock⁴⁴ (case 3), Peacock⁴⁵ (case 4), Foster⁴⁰ (case 2), Allbutt⁵⁴ (case 1), Burney-Yeo⁶⁰ (case 2), Peter⁶¹ (case 1), Peter⁶² (case 2), Oiton-M'Aldowie,⁶⁷ Zohrab,⁷⁵ Cantley,⁸⁴ Launois,⁸³ Debove,⁹⁸ Ostwalt,⁹⁹ Horton-Smith,¹⁰² Dupuis¹⁰³ (case 1), Taylor,¹⁰⁴ Shaw,¹⁰⁵ Jorns,¹⁰⁸ Ercklentz,¹¹¹ Oliver,¹¹² Anderson¹¹⁸ (case 1), Allbutt¹²⁴ (case 3), Wolvins,¹³⁵ Emanuel-Roncoroni¹³⁶) Markham's case,³⁹ which was the only one in this group which came to autopsy, was in my opinion one of aortic insufficiency, due to an endocarditis of the aortic valve and not to rupture. Others besides Markham have made a similar mistake. Thus, no less a clinician than Gerhardt¹¹ reported a case of supposed rupture of the aortic valves, which later Sinnhuber¹¹⁵ stated was shown at autopsy to be due to a recurring endocarditis of the aortic valve and not to rupture. It is, therefore, wise to regard no case as acceptable without an autopsy record.

In the second group there are forty-seven cases recorded, but only fourteen were proved by autopsy (Bouillaud - Beigeon,³⁰ Wilks,⁴⁶ Hayden,⁵⁰ Finnell,⁵¹ Foster⁵⁶ (case 3), Duroziez⁶⁸ (case 1), Barié-Potam,⁷² (case 3), Madei,⁷⁶ Biggs,⁸⁰ Strassmann,¹⁰⁷ Schmidt,¹⁰⁰ Tranquilli-Deganello,¹²⁰ (case 2), Stemitz,¹²⁵ Meyer¹³⁴) The Bouillaud-Tallall²⁹ case came to autopsy, but, in my opinion, the perforation of the valve was not necessarily traumatic. In the other thirty-two, no autopsy was obtained after death, or the patients were still alive at the time the case was recorded (Leroy,⁶⁴ Duroziez⁶⁹ (case 12), Barié⁷⁰ (case 1), Barié⁷¹ (case 2), Barié⁷³ (case 4), Heidenham,⁸⁵ Dieyfus,⁸⁶ Dufou,⁸⁷ Bernstein⁹⁰ (case 1), Bernstein⁹¹ (case 2), Bernstein⁹² (case 3), Lembke,⁹³ Schneider,⁹⁴ Guder,⁹⁵ Kantorowitz⁹⁶ (case 1), Kantorowitz⁹⁷ (case 2), Castiaux and Laugier,¹⁰¹ Calwell-Campbell,¹⁰⁶ Cahn,¹¹⁰ Sinnhuber¹¹⁵ (case 1), Sinnhuber¹¹⁶ (case 2), Sinnhuber¹¹⁷ (case 3), Schlecht¹²¹ (case 3), Schlecht¹²² (case 4), Zulzer,¹²³ Hoffmann¹²⁶ (case 1), Hoffmann¹²⁷ (case 2), Hoffmann¹²⁸ (case 3), Bensaude-Monod,¹³⁰ Cramer,¹³¹

Brossard-Heitz¹³² (case 1), Brossard-Heitz¹³³ (case 2))

In the third, small, group of six cases the exciting cause was not stated, though all revealed at post-mortem a rupture of one or more of the aortic valves with a resulting aortic insufficiency, (Corrigan²⁶ (case 1), Rokitsansky³⁸ (case 39), Bennett,⁴² Ellis,⁴³ Humphrey,⁷⁴ Fisher¹¹³) However, Fisher's case is so incomplete as to be unacceptable.

To summarize, we have records of 113 cases of rupture of the aortic valve, of which forty-nine were proven by autopsy. Of the two main groups, the "strain" group is the larger, comprising altogether thirty proven and thirty unproven cases compared with fourteen proven and thirty-three unproven cases in the traumatic group. In five acceptable cases the cause for the rupture was not stated.

PREDISPOSING FACTORS

Country and race. Among the "strain" group, sixteen proven and seventeen doubtful cases were reported from Great Britain, seven doubtful from France, eight proven and three doubtful from Germany, one doubtful case each from Italy and Holland, three proven cases from America, two proven and one doubtful case from Canada, and one proven case from Australia. As may be seen, therefore, by far the great majority of the proven and doubtful cases were reported from Great Britain.

In rather marked contrast is the geographical incidence of the "traumatic group" only four proven and one doubtful case from Great Britain, two proven cases from America, and one from Italy, while from France three proven and eleven unproven cases, and from Germany five proven and twenty-one unproven, are recorded. In this group, therefore, Germany leads, with France second. In the third group, four cases (three proven) came from Britain, and one each from America⁴³ and Austria.³³

Sex. Of the forty-nine proven cases of the three groups, the overwhelming majority (98 per cent) were males. In fact, only one female is listed among the "strain" cases and that doubtful, while among the traumatic cases, there were but three females, two of which were not proven cases. Evidently, therefore, the male

sex is more exposed to rupture of the aortic valve than the female.

Age Of the "strain" group the age was stated in twenty-six of the proven and in twenty-six of the doubtful cases. In the former it ranged between 20 and 60 years with a mean of 37.2 years, in the latter from 20 to 68 years, with a mean of 37.4 years. The most susceptible decades were the fourth and fifth in both sub-groups. In those of the "traumatic" group, in which the age was stated, the range varied from 19 to 85 years in the proven cases, a mean of 45.6 years, while in the unproven group the variation was less marked (10 to 60) years, with a mean of 35 years. The most susceptible decades here also were the fourth and fifth. In short, the point of interest is that in the strain group the mean age was 37.2 years, in contrast to a slightly higher mean age for the traumatic group of 45.6 years.

Occupation In the strain group of the thirty proven cases, the occupation is mentioned in twenty-seven, of which all but five (physician, apothecary, cook, clerk, and bar-tender) were exposed to constant or occasional muscular effort in their daily routine, for example, five were day-labourers, two dock-labourers, one brakeman, one butcher, one chauffeur, etc. In the unproven cases, the occupation was mentioned in twenty-nine, and in only six was the occupation of the non-laborious variety, of the six latter, the most interesting case occurred in a young pregnant mother during the act of labour. Among the arduous occupations are also mentioned, two day-labourers, two farmers, a ship-wright, a carpenter, a smuggler, a poacher, a bricklayer, etc. In short, in this entire group, 81 per cent of the cases occurred in occupations which exposed the patient to great muscular effort.

In the traumatic group, among the fourteen proven cases, the occupation is not mentioned in four, in the other ten cases (80 per cent), their occupations exposed them to injury. Thus, two cases were carters, two labourers, one soldier, one ship's-cook, one jockey, one coachman, etc. In these occupations, four sustained a fall to the ground from various heights, three were kicked by a horse, two received a blow on the chest from a fist or a piece of iron, and one was squeezed between a post and a cart-wheel.

In the unproven sub-group, there was the same variety of occupation, though in the great majority it was of the arduous type. Among the twenty-eight cases whose occupation is given there were four labourers, four soldiers, one miner, one sailor, one locksmith, one stonemason, etc. Here by far the commonest cause for injury was a fall (sixteen cases) and next in order of frequency, a blow from a blunt instrument (ten cases), a not infrequent cause was a crushing injury to the chest wall (five cases).

Past medical history The patients' history, as to alcoholic excess, syphilis, rheumatic fever, chorea or tonsillitis, and previous cardiac symptoms, is of course of great importance in determining a possible *locus minoris resistentiae*. This question will, therefore, be discussed before taking up the more accurate pathological criteria.

In the strain group, among the thirty proven cases, alcoholic excess is admitted in three cases only, denied in three, and not mentioned in the remaining twenty-four patients. In the doubtful cases, alcoholic excess was reported in four, absent in two, and not mentioned in twenty-four.

In the traumatic group the histories are more incomplete, even in the proven cases, but an abuse of alcohol was given in three cases before, and in one case after the accident, in ten histories no mention is made of alcohol. Of the thirty-three unproven cases, no one admitted to excess of alcohol, one denied it, and in the thirty-two other reports, no mention is made of it.

In the third main group which consists of five cases, in which the exciting factor is not stated alcohol is not mentioned. In short, neither in the strain nor traumatic group does alcoholic excess play an important rôle.

In the strain cases which were proven, venereal disease was admitted only in the Frew-Finlayson case,⁹⁹ who had a chancre at 18 years of age, but without rash, in seven other cases it is specifically denied, and in twenty-two it is not mentioned in the history. In the unproven cases, syphilis appears five times in their records, (Zohrab,⁷⁵ Horton-Smith,¹⁰² Dupuis,¹⁰³ Taylor,¹⁰⁴ Emanuel-Roncoroni¹⁰⁶), though at the time of the accident the blood Wassermann was negative in one patient, in four others venereal

disease is denied, while in twenty-four histories no mention is found. Syphilis, therefore, in the strain cases does not appear as prominently as one might expect from the well-known predilection of syphilis for the aortic valve

In the traumatic group, among the fourteen proven cases, there is no case of known lues, in three it is denied and in eleven others no mention is made of it. Among the thirty-three unproven cases, one admitted to gonorrhœa (Sinnhuber¹¹⁷ (case 3)), eight denied venereal disease and in twenty-four no mention is found.

In the third main group of five cases, venereal disease is not mentioned.

Rheumatism, chorea and tonsillitis, which are so important in the etiology of endocarditis, were present in five cases, negative in eleven, and not mentioned in fourteen of the strain group proven by autopsy. Arteriosclerosis existed in one case⁷⁹ of this group and had no doubt weakened the valve. Pulmonary tuberculosis, malaria, and possibly, a chronic infection from chronic eczematous ulcers of the legs occurred in each of three cases, and may have had a predisposing influence.

Among the thirty unproven cases in the strain group, rheumatic fever was present twice and chorea once, while in thirteen cases rheumatism is denied, and in fourteen others it is not mentioned. There was, however, a history of malaria twice, sepsis twice, pneumonia twice and influenza once, diseases which might have lowered the resistance of the aortic and valvular tissues. Hence in only seven of the entire group of 60 cases was there presumably a previous rheumatic endocarditis.

In the traumatic group, even among the proven cases, there was no case with a history of the rheumatic cycle, in three it was denied and in eleven no mention is made of it. One case (Tianquilli-Deganello¹²⁰) had furunculosis five years before the accident, and so, possibly, septicæmia. Of the thirty-three unproven cases one⁹⁶ had rheumatism since the accident, two others^{37 122} before the accident, and one⁹⁵ had rheumatic purpura, in fourteen others the disease is denied, while in fourteen histories no mention is made of it. Hence, in the traumatic group of forty-seven patients, only four had, possibly, an aortic valve damaged by a previous attack of rheumatism. Two women^{29 86} had repeated pregnancies, while two males had a pre-

vious malaria,^{69 117} one measles and influenza⁸⁶ and one influenza alone,⁸⁷ while one patient had an active tuberculosis¹²³ and another was in the midst of a pneumonia,¹²⁸ when he fell out of bed.

In the third main group only one patient admitted to chorea⁴³.

Previous heart symptoms. Symptoms suggestive of a pre-existing valvular disease were present in only two cases^{58 79} of the strain group proven by autopsy, in eleven others they were denied, while in seventeen of this group no mention is made of their existence. Presumably, therefore, though not conclusively, in only two cases did a valvular defect of any degree exist prior to the strain. Among the thirty unproven cases of this group there was a history of previous cardiac symptoms in three^{75 84 103} of the twenty in which this point is mentioned. Again, but a small minority had pre-existing heart disease, though, of course, only an autopsy would corroborate this belief.

Among the fourteen proven cases of the traumatic group in five it is stated previous heart symptoms were present, while in the other nine cases no mention is made of the previous state of the cardiac compensation. In the thirty-three unproven cases twenty-one definitely denied them, and in twelve no mention is made of them in the scanty case reports.

In the third main group previous heart symptoms are not mentioned.

MORBID ANATOMY

First, as to the cusp affected. Because of the great variation in the anatomical nomenclature for the aortic valve we had great difficulty at times in deciding which of the three aortic cusps was the one ruptured. The anterior aortic cusp is usually called the "anterior," sometimes the "septal" or "segment of closure", the right posterior cusp of Gray's Anatomy is sometimes called the "posterior" and sometimes the "mitral", the left posterior aortic cusp is frequently spoken of as the "middle" cusp. We have reduced all these terms to "anterior," "right posterior" and "left posterior" cusps. It is important to remember that from just above the anterior cusp the right coronary artery arises, and

from above the left posterior the left coronary arises

While usually only one cusp is torn, sometimes two, and, rarely, three are affected. In the strain group, only one cusp was affected in eighteen cases, two in ten, and all three in two cases.^{57 78} When only one cusp was involved, it was the anterior in seven cases, the right posterior in four, and the left posterior in two, in five other post-mortems the ruptured cusp is not specified. When two cusps were affected, it was the anterior and right posterior in two, the anterior and left posterior in one, and the right and left posterior cusps in two, in five other protocols the two cusps affected are not mentioned.

In the traumatic group, which comprised but fourteen cases, only one cusp was involved in ten, and two cusps were affected in four. Of the single cusp cases, in five protocols the exact one is not specified, while in two it was the anterior, in two the right posterior, and in one the left posterior. When two of the cusps were involved it was the anterior and right posterior in two, and the right and left posterior in two. There was no example of traumatic tear of all three cusps.

In the third small group of cases in which no exciting factor was stated, all five came to autopsy, of these the left posterior cusp was alone affected in two, while both the anterior and left posterior were simultaneously torn in two cases, and in one case the cusp affected is not specified.

From a study of these figures the most frequent single cusp to be involved is the anterior (nine cases), next, the right posterior (six cases), closely followed by the left posterior (five cases). If one, however, considers the cusp which may be most frequently torn, either singly or in combination with one or two other cusps, we find the anterior is still first (eighteen cases), the right posterior is next (sixteen cases), and the left posterior last (fourteen cases). This finding is somewhat contrary to the early teaching that it is usually the posterior cusps that are torn, but is quite in accord with the statement of Barié,⁷⁰ who found the cusp most frequently involved to be the anterior (which corresponds directly with the interventricular septum), as was seen in one of his seven experiments.

The site of the tear. There may be a rupture of the cusp itself (eleven cases), either at its free border or at its base, and but rarely in the middle of the cusp. As a rule, however, it is a vertical or longitudinal tear of the endocardium, or, rather, of the intima of the aorta, with a consequent displacement of the cusps (thirty-seven cases). As Peacock⁴ wrote in 1873, "It may be that the angles of one or more of the segments are torn from their attachment, or the convex edge of the valve may be separated from the fibrous zone, or the curtain may be torn through."

In our series the strain group revealed only three cases of rupture of the cusp itself, in contrast to nine due to a tear of the angle of attachment, and to sixteen due to a tear of the intima of the aorta near the base of the valve. In the traumatic group there were eight cases of rupture of the cusp itself, to only one of its angle of attachment, and to six of the intima of the aorta. In the small unclassified group, we find no case of rupture of the cusp itself, two of the angle of attachment, and three of the intima near the base of the valve. In the entire series, while the commonest site was a tear of the intima near the base of the cusp (twenty-five cases), rupture of the cusp itself, or of its angle of attachment, being almost equally frequent (eleven of the former and twelve of the latter), we seem justified in concluding that the cusp itself is more apt to be ruptured in direct traumatic cases, and the angle of attachment or the intima of the aorta near its base in the muscular strain group.

Now, as to the state of the valve itself at the time of the autopsy (but not necessarily at the time of the accident), in the strain group it was normal seven times, thickened or atheromatous eighteen times, once with evidence of fresh endocarditis, and four times its condition was not mentioned. In the smaller traumatic group the aortic valves were normal six times, thickened or atheromatous five times, with fresh endocarditis once, and twice their condition is not mentioned. In the third, very small, group the state of the valve is only mentioned in four cases, in three it was thickened or atheromatous, while in one it was covered with recent vegetations. What was specially interesting was that two cases re-

vealed a congenital anomaly of the valves^{43 74}

To summarize, therefore, in only thirteen of forty-eight autopsies, or 27 per cent of the entire series, was the aortic valve reported as absolutely normal, but it was more frequently normal in the traumatic group (44 per cent) than in the strain group (23 per cent). In the great majority of the protocols the aortic valves are described as thickened, atheromatous, or even calcareous. In two cases,^{33, 72} there was evidence of a fresh endocarditis in addition to the rupture, but in both cases it was probably of more recent origin.

The state of the aorta, and especially of the intima near the mouths of the coronary arteries, is of course of great interest. In the strain group the aorta was reported as normal in three cases, smooth but dilated in two and atheromatous in sixteen cases, in three of the atheromatous group there was some dilatation, and in one an aneurysm of the ascending aorta,¹¹⁴ while in two^{37 83} others the mouth of one coronary was obliterated by a patch of atheroma. In the traumatic group, the aorta was both actually and proportionately more frequently normal (five cases), though in one of these it was dilated. In only four cases was there atheroma and in one of these there was also moderate dilatation. In one case of this group¹⁰⁹ there were multiple tears of the thoracic, and a single tear in the abdominal aorta. In the third, or unclassified, group the aorta was atheromatous in two. Unfortunately, no statement about the condition of the aorta was found in nine of the strain group, four of the traumatic and two of the unclassified. In Corrigan's²⁶ case only was the process in the aorta suggestive of syphilis, as the aneurysm in Heller's case¹¹⁴ resembles more a dilatation than a syphilitic one. In general, therefore, the aorta was much more frequently the site of atheroma in the strain group (sixteen cases) than in the traumatic.

As to the state of the heart itself it was reported as hypertrophied in eleven, dilated in six, and both dilated and hypertrophied in nine of the strain cases, in not a single case was it normal, though in four cases the exact state of the heart was not stated. In the traumatic group, on the other hand, it was hypertrophied in one, dilated in three and both hypertrophied and dilated in six, in one case it was said to be

atrophied, while in three cases its condition is not stated. In the unclassified group it was found hypertrophied in two and not stated in three. In short, hypertrophy of one or both ventricles was the rule in all three groups, though frequently dilatation also existed. As to the condition of the myocardium itself, fatty or fibroid degeneration was reported in five cases of the strain group and two cases of the traumatic group. In addition, there was an abscess in the wall of the left ventricle in one case,¹³⁴ an aneurysm of the mitral valve in another,³⁷ two aneurysms of the right auricular appendage in another,⁸² and an adherent pericardium in another case.¹⁰⁷

The usual evidence of cardiac decompensation was found in many cases, especially venous stasis of the lungs, liver and spleen, in two cases hydrothorax, and in two other cases effusions into two or more of the serous cavities, were present. Pulmonary infarction occurred in but two cases,^{67, 137} thrombosis of the right axillary and brachial artery in one case,¹⁰⁰ and a thrombosis of the posterior tibial vein in our own case.¹³⁷ As might have been expected in the traumatic cases, laceration of the parenchymatous organs, liver and spleen or of the intestine occurred twice^{30 109} and once⁴⁶ respectively. In this same group, fracture of the ribs,³⁰ dorsal vertebrae,^{30 109} or of skull was also present in the odd case. An occasional finding was healed or active tuberculosis of the lungs.

PATHOGENESIS

Muscular effort or strain may result in rupture of a healthy valve, though this is naturally a rare event according to both Romberg and Allbutt, and, as already stated occurred only seven times in our series. Muscular effort may lead to rupture of an aortic cusp more readily in a valve previously the site of rheumatic or syphilitic or arteriosclerotic disease, in fact many authorities recognize only this group. Of course, many of the case reports are so lacking in detail as to leave themselves open to the doubt of the presence of some previously existing gross, or at least microscopical, lesion. Lastly, muscular effort or strain may result in repeated mild attacks of valvulitis, and so predispose to subsequent rupture of the valve.

In answer to the question how muscular

effort causes rupture of a valve, Barié⁷⁰ states that during the effort the thorax is filled with air but is immobilized, and the intra-aortic tension is considerable, because during each diastole of the heart the aorta has to support an extreme pressure. Pepper⁵⁸ offers a somewhat similar explanation, "Immediately before the effort, whether at striking, or lifting heavy weights, a deep inspiration is taken, which aids in filling the cavities of the heart to their utmost, and then in order to afford fixed points for the contraction of the muscles of the arms and shoulders and back, the chest is held rigidly fixed. The violent contractions of the neck which follow compress the carotid arteries, while those of the muscles connected with the arms impede the free flow of blood through the subclavians and their branches. Thus, while the tension within the chest is greatly increased and the heart is stimulated to violent contraction, there is also an enormous elevation of arterial tension. The strain which results must extend itself directly upon the walls of the left ventricle, which must over-exert themselves to press forward the blood, and indirectly upon the aortic valves, which are compelled to bear the shock of a recoil of the blood stream violent in proportion." Heller¹¹⁴ believes the explanation of the fact that the predilection site of the tear during muscular effort is the first portion of the aorta is that in many persons the trachea is attached just above the aorta, and that the right bronchus in spastic respiratory arrest is pressed against the aorta. According to Potain, it requires a pressure of twenty to twenty-five c.c. of mercury to break the aortic valves. Barié's⁷⁰ experiments on the cadaver are of great interest. By increasing the intra-aortic pressure until it reached from 116 to 484 mm. of mercury, in ten cadavers dead from various non cardiac diseases, he was successful in producing rupture of one or other of the aortic cusps in four, in two the septal segment (anterior), and in two the left segment (left posterior) were torn.

Trauma may result in rupture of an aortic valve segment, either (a) as a result of a contusion of the chest wall from a kick or a blow or compression of the chest, or (b) as a result of a violent shock to the body from a fall from a height. It must, however, be admitted, with

Allbutt, that in the history of some of these accidents the distinction between the outer and inner stress cannot be made, but probably in all the mechanical process is similar, the external blow violently compressing the thoracic cage.

Barié⁷⁰ and Potain experimented on the cadaver by administering three blows from a hammer on a board fixed to the præcordium. In two out of the five cadavers rupture of the aortic valve occurred, once in the median segment (left posterior) there developed an oblique tear extending from its free border to the attachment, and once a tear of the septal (anterior) cusp.

Dufour⁸⁷ has produced in four dogs a traumatic rupture of the aortic valve. His method was the administration of one to four blows with a mallet over the præcordium, post mortem, several ribs were found broken and in all four dogs the water-test of the aortic ring was positive, the other valves were normal. In the first dog there was a tear of the right posterior and right anterior cusps, in the second dog all three cusps were torn, in the third, rupture of the right posterior had occurred at the insertion, in the fourth dog he found rupture of the right posterior cusp, from its free border to its base, and separation of the left posterior cusp from the aorta.

Kuelbs,⁹ in 1909, used a 40 cm round meat-hammer, weighing 150 grams, and gave one to three sharp blows over the left thorax, the force of which as read by a dynamometer varied from 140 to 180 kilograms or more. The dogs revealed no evidence of pain, but merely of anxiety and shock. Two died spontaneously after the blow, the others were killed by bleeding and chloroform. The pulse was noted as rapid and irregular, heart murmurs became audible in six of the dogs. Post mortem, there were occasional small hæmorrhages into the pericardium, but more often hæmorrhages into the valvular endocardium, especially of the semilunar valves, a tear of an aortic valve occurred only once and that near the nodulus Arantii of one segment. There was often hæmorrhage into the myocardium. In short, 28 of the 34 dogs, or 82 per cent, showed valve hæmorrhages (mitral 12, aortic 7, pulmonary 4, tricuspid 5). Normal heart sounds were sometimes present when the post-mortem revealed a hæmorrhagic valve.

FISH TAPEWORM*

INTESTINAL INFECTION IN MAN THE INFESTATION OF FISH IN MANITOBA LAKES.

BY DANIEL NICHOLSON, M D, M R C P (LOND),

*Assistant Professor of Pathology, Faculty of Medicine, University of Manitoba,
Assistant in Pathology, Winnipeg General Hospital,
Winnipeg*

TAPEWORM infection has always had an unusual interest because of the great size of the parasite. This has led to an early discovery of its life cycle. The main varieties affecting man occur from eating larva-infected beef, pork or fish. Hitherto, the types derived from beef and pork have been commonest in this country. Now, however, they are becoming rarer, while the fish type is becoming more frequent, and it is the most serious of the three.

The symptoms of tapeworm infection vary greatly. A voracious appetite is the exception rather than the rule. Some desire only highly seasoned food. The symptoms of which a tapeworm-infected patient may complain are common to many abdominal diseases. They are colicky abdominal pains, alternating constipation and diarrhoea, nausea, particularly when the stomach is empty, dizziness and neurosis. Frequently, symptoms appear about the time the patient notices the first segments of worm in the stool. There are no typical signs of tapeworm infection. Eosinophilia is present in so small a percentage of cases that it is not valuable in diagnosis.

Two most important points in the diagnosis of fish-tapeworm infection are first, to ascertain whether the patient ever eats uncooked fish which is likely to be infected, and second, if segments of the worm have been noted in the stool. Fish-tapeworm segments may be readily differentiated from those of other varieties of tapeworm, they are broader than they are long and the uterus forms a small yellowish dot in the centre.

Patients who pass large segments of the worm at frequent intervals rarely have anæmia. The anæmia occurs in only about 1 per cent of those infected, and it may vary from a very slight to the most profound pernicious aplastic type. A person may be infected with fish-tapeworm for

several years before developing anæmia. It is a remarkable fact that in patients who suffer from anæmia due to tapeworm the segments are rarely cast off in the excreta but undergo degeneration in the bowel. To exemplify, the following cases are briefly reported.

CASE 1

A. P., aged 11 years, of Scottish extraction and born in Winnipeg, entered the Children's Hospital under the care of Dr O. J. Day complaining that during the past 6 or 7 months she had passed about 40 feet of tapeworm. She had an eager appetite, was losing weight, and was becoming nervous.

Treatment by purgation and Felix mas caused the patient to pass a worm nine feet in length with the head intact. Examination of the segments which were three times as broad as long showed a rosette uterus containing oval eggs. This would definitely identify the worm as *D. latum*. This is the first case of *Diphyllobothrium latum* infection in a patient born in Winnipeg that has come to my notice.

CASE 2

Mrs S. B., 57 years of age, a Jewess who had come from Russia twenty-two months before, was admitted under Dr Charles Hunter's service to the Winnipeg General Hospital, May 27, 1926. She complained of the passage by bowel of long, white, ribbon-like strands, nausea, and abdominal discomfort. Two months previously, and seven months previously, she had passed segments several yards long. For the past seven months she had been nauseated and her appetite poor, she could eat only highly seasoned food. She had lost twenty pounds in the preceding year.

She was a healthy looking woman who showed no physical signs of any importance. A blood examination showed 65 per cent hemoglobin and 3,600,000 red cells, giving a colour index of 0.9. The blood smear showed a definite variation in size of the red cells. There was no irregularity of outline, but some achromia was present. The white cell differential count was normal, the eosinophiles constituting only 2 per cent. A vermifuge was followed by a large mass of fish tapeworm and one head.

CASE 3

S. Z., consulted Dr A. Hollenberg in October, 1927, complaining of weakness and pallor. He had not been digesting his food well during the past several years, and in 1924 his appendix had been removed for this but without relief. He had come from Russia in 1922.

Physical examination showed a well developed man with a yellow tinge to his skin but in other particulars was essentially negative. There were no nervous or sensory disturbances. A blood examination showed a hemoglobin content of 65 per cent and 2,500,000 red cells, giving

* Received for publication, May 1 1928

a colour index of 1.3. The white blood cells were 8200 per c mm and an examination of the blood smear showed an unusually large percentage of eosinophiles. A saline purge, before and after male fern as a vermifuge, caused the patient to expel about twenty feet of *Diphyllobothrium latum*.

CASE 4

V. P., a young man 22 years of age, who came to Canada from Finland a year ago, developed in the last five months a severe anaemia of the pernicious type. After coming to Canada in February, 1927, he stayed in Vancouver for two months and then came to Manitoba, where he worked near the San Antonio mine. On December 30th he was admitted to the Winnipeg General Hospital under the care of Dr. A. J. Burrage. He complained of alternating constipation and diarrhoea, weakness, blurred vision and he noticed that his skin was pale. In June, while working in the bush, he began to have alternating constipation and diarrhoea, each lasting three or four days. When constipated he would vomit frequently after a meal. At no time did he notice any worms, blood or pus in his stool. Along with the gastrointestinal disturbance he had a poor appetite and suffered from progressive weakness. Two weeks before admission to hospital his pallor was so marked that he noticed it himself. His face was swollen and his vision blurred.

Blood examination showed a severe aplastic anaemia with haemoglobin of 21 per cent (Newcomer method), red cell count 1,200,000, platelets 45,000, and white cells 3,700 per c mm. The smear showed 3 per cent eosinophiles. The red cells in the spread were very scanty and showed great variation in size, with many large forms and a marked hyperchromia of all except the very small cells. (See Fig. 1).

Examination of the stools by the concentration method showed numerous ova, as in Fig. 2. Only by this examination could a correct diagnosis be made in this case.

FIG. 1—Blood film from Case 4 ($\times 500$, 1 mm = 2μ) showing scanty hyperchromic cells with great variation in their size and many large forms.

EXAMINATION OF FECES FOR OVA

This examination is very important and is easily done, but because we do not like to examine faeces it is too frequently neglected.

The examination, as usually done, often consists in viewing a very small particle of excreta under the microscope for a moment and rendering a negative report. Ova will frequently be missed by such an examination.

A concentration method is best. It depends on the rapid settling of the ova. The following is the least objectionable and most easily performed. Because of its importance I shall describe it in detail. Do not order a purge before collecting the specimen. Collect a mass of faeces, somewhat larger than a hen's egg, in a quart-sized, wide-mouthed fruit-sealer containing an ounce of formalin and a pint of water. The formalin destroys the disagreeable odour, which is the greatest objection to the examination of faeces. Break up any firm masses with a spatula. Cover the jar tightly and shake it vigorously for half a minute. Allow two minutes for the sediment, which consists of faecal particles and ova, to settle. Pour off the supernatant fluid, and again fill the jar two-thirds full with fresh water. Cover and shake as before. Then, strain the contents through a layer of coarse gauze into another glass jar. Most of the ova will go through the gauze but the large particles of faeces will be held back. The ova are heavy

FIG. 2—Ova of fish tapeworm as seen with the low power lens and $\times 10$ ocular ($\times 100$).

and they settle as a dark brown sediment in less than two minutes. Transfer a drop of this sediment by means of a pipette to a glass slide. Put on a cover glass and examine under the low-power lens of the microscope with subdued light.

When ova are present no doubt exists even in the mind of one unacquainted with their appearance. They appear as numerous large oval bodies of uniform size and shape (see Fig 2). The outer membrane is thin and more than a dozen spheres make up the contents. By pressing the cover slip the membrane at one end sometimes separates like a lid and the contents of the ovum may be extruded. There are no other particles in the faeces so unvaried, and if one is in doubt whether or not a few irregular, roundish bodies are ova it is almost certain they are not.

INCIDENCE IN WINNIPEG

The records of the Winnipeg General Hospital show 15 cases of fish tapeworm infection during the past four years. Five of these occurred during 1927. The three cases of associated anaemia noted would make an unduly high percentage. This may be due to the small series or to the presence of anaemia making an infected patient seek hospital care. The hospital records have no index of diseases from 1912 to 1923. Previous to 1912 the annual reports which date back as far as 1886 contain a classified list of the diagnoses with the number of cases of each disease. The earliest mention of a tapeworm was in 1892 and that was a *T. solium*. From that date till 1912 one to five cases of *T. solium* or *saginata* occurred yearly. The irregular sequence of these would lead one to question the classification of type. There was no mention of fish tapeworm.

The infection is frequently treated out of hospital sometimes by giving a vermifuge as a therapeutic test so that the records stated are only a fraction of the total incidence. Although this is true and the hospital capacity has increased from 125 beds in 1892 to 650 beds in 1927 the infection is probably on the increase.

MODE OF SPREAD

Tapeworm infestation is commonest among our new Canadians from Russia and other countries around the Baltic Sea as they still have the habit of eating uncooked fish with salt. Of all the cases noted only one was native born. The longest residence in Canada was eighteen years. Many are fishermen and, if infected, the ova from their excreta soon reach our lakes. Dogs may also act as hosts.

It is very striking that the tapeworm infestation occurs in many Jewish women but not in Jewish men. This may be attributed to the women handling the fish before it is cooked, or, probably, it is due to their tasting a special dish called "Gefilte" fish, to determine the correct amount of seasoning before cooking it. This is prepared by mincing fish with onions, peppers and other spices, rolling it into cakes, which are covered with the fish skin and then cooked.

Very probably Cases 2 and 4 had the tapeworm before coming to this country. Dr A. Hollenberg found that all the infected patients he saw in 1927 ate herring imported from Norway. Previously, when their herring supply had been brought from Alaska, no cases had come to his notice. However, as the pike and pickerel from Lake Winnipeg are definitely infected, human infection will develop from eating them uncooked.

THE LIFE CYCLE OF THE PARASITE

Starting as the larval form in the flesh of fish, the fish tapeworm, *Diphyllobothrium latum*, formerly known as *Dibothriocephalus latus*, when eaten uncooked, will attach itself by the sucker slits in its head to the small bowel of man, dog, cat or fox, and grow, developing segments very rapidly. It comes to maturity and casts off eggs in from three to four weeks. Each segment has in its central part a uterus and ovaries, and in its peripheral part testes and vas deferens, so that each ovum is fertilized as it leaves the genital opening in the segment. The worm may live for several years. When many are found in one individual they frequently do not attain the great size and length that a single one does, though Dr J. C. Todd¹ has reported a patient who had six tapeworms, totalling seventy-five feet in length and then

FIG 3—Head of small tapeworm (\20) from intestine of the pike

flesh also showed them in their viscera, chiefly in the liver, peritoneum, or egg-sac. These were not recorded or used for feeding experiments, because only larvae in the flesh are dangerous to man.

The method used was first to remove the skin of the fish and then, with a very sharp knife, pare off thin slices. When the larva is present it is easily seen with the naked eye. It appears as a tiny, opaque, white worm, less than 1/16 of an inch wide and from 1/8 to more than 1/4 of an inch in length, and may be lying straight, bent on itself once, or coiled up. The fish flesh is very translucent in contrast with the opaque worm. This contrast is increased by pressing the fish flesh between glass plates. Even after the fish had been in

FIG 4—Large larva from infected pike (\13) showing segments and the head withdrawn. The tail was curled around in an air bubble.

FIG 5—Larva from infected pike (\28). The head is withdrawn and appears as a round mass at the right. The body movements blur the photograph.

cold storage for months, most of the larvae moved about when freed from the muscle and subjected to the warm temperature of the room. A drop of warm water made them especially active. The larger forms contained definite segments and a head that would retract to form a large rounded ball (Fig 4). Then the head as a tiny point would extend from the centre. This would be followed by the body of the worm drawing itself up to the extended head. Some of the heads showed a longitudinal slit.

The larval form photographed in Fig 5 was very active. A contraction-wave would pass down from the head to the tail and there was side-to-side motion as well. Under a magnification of 100 diameters, one could easily discern a streaming of granules, most rapid at the point of contraction, and moving towards the head, while the contraction moved in the opposite direction. This produced some blurring in certain areas, even on quick exposure. On adding a drop of 5 per cent carbolic acid this larva

FIG 6—Larva pictured in Fig 5, after applying a drop of carbolic acid to stop its movements (\13).

shortened itself up and ceased moving, when Fig 6 was taken

IDENTIFICATION OF ADULT TAPEWORM BY FEEDING EXPERIMENTS

Finding larvæ, as already described, in the flesh of fish does not prove that they are *D latum* (*Bothriocephalus latus*). Only by feeding these larvæ to dogs can the adult form be developed and identified. Slices of fish muscle containing fish larvæ were used for these experiments. The larvæ were not dissected out and counted. Altogether six dogs were used for the experiment but two had to be discarded, one because he would not eat fish, and the other because he was already infected with tapeworm (*Tænia solium*). Strict precautions were taken at the beginning of each experiment to make sure that the animals were not already infected. The dogs were put in separate cages and three consecutive specimens of stool from each dog were examined for ova or segments of intestinal parasites. The one which was infected showed ova on the three examinations, and later a vermifuge caused four well-formed specimens of pork tapeworm to be expelled. The other dogs, although their stools showed no ova, were given a vermifuge as an extra precaution. This consisted in omitting the evening meal and administering one-half ounce of magnesium sulphate by means of a stomach tube passed through a hole in a wooden bit which is held firmly between the dog's teeth. Next morning a dram of liquid extract of male fern, made up into an emulsion, was administered in the same manner, and at noon a final half ounce of magnesium sulphate was given. None of the dogs used for the experiments passed any segments of tapeworm. The dogs were then fed on puppy biscuits for two days to remove any trace of the anthelmintic that might remain and kill the larvæ in the fish. After eating the infected fish they were fed wholly on dog biscuits to avoid any possibility of tapeworm infection from other sources. Two of the dogs were used for

physiological experiments and the gastrointestinal tract later removed for examination. I am much indebted to Dr. Moorhouse, Professor of Physiology, for his help and co-operation in the animal experiments.

Dog No 1 would only nibble at scraps of the infected fish. I did not think he would be infected in this manner, so he was used in physiological experiments nine days after the feeding. His ileum contained 1 *D latum* with a typical head as illustrated in Fig 7. The segments

FIG 7—Typical head of fish tapeworm showing lateral slit ($\times 30$) from dog No 1. The shape of the heads varies, especially where there are multiple parasites. Many are heart shaped but all have the lateral grooves.

Many are heart shaped but all have the lateral grooves. The heads were of typical shape and a development of a central uterus was beginning in the end segments.

Dog No 2 would gulp down large portions of the infected fish, so he was fed about a pound of infected slices of pike on three consecutive days. More than five weeks elapsed before ova appeared in the stool. This prolonged time was probably due to the large number of worms in

FEEDING EXPERIMENTS WITH THE LARVÆ (plerocercoids) FOUND IN THE PIKE (*Esox Lucius*) AND PICKEREL (*Stizostedion vitreum* MITCH.)

Dog	When Fed Larvæ	Variety and Origin of Fish	Date of Examination	Result
No 1	Feb 8	Pike, L. Winnipeg	Postmortem, Feb 17	1 <i>D latum</i> , 8 inches long
No 2	Feb 8	Pike, L. Winnipeg	Postmortem, Mar 29	19 <i>D latum</i> , 18-40 inches long
No 3	Feb 12	Pickrel, L. Winnipeg	Vermifuge, March 31	5 <i>D latum</i> , 2 heads, 1½ to 2½ ft. long
No 4	Mar 5	Pike, I. Manitoba	Vermifuge, April 7	8 <i>D latum</i> , 6 heads, 2 to 3½ ft. long

FIG 9—Coils of intestine containing strands of fish tapeworm. The arrows point to the position of the heads. The stomach and caecum may be seen below. Taken from dog No 2.

the intestine. When many are present they do not grow as rapidly or as large as does a solitary worm. Post-mortem examination, seven weeks after infection, showed 19 heads in the ileum. The bodies of all these worms made a cord about half an inch in diameter. Fig 9 shows the intestine containing the parasites. This dog showed many typical ova in his stools for the previous ten days.

Dog No 3 was fed muscle of pickerel containing larvae. Typical ova appeared in twenty days. They were present in great numbers, but no worm segments were passed. Blood examination showed no anaemia three weeks later. He was given a vermifuge forty-eight days after the feeding of the pickerel. Five tapeworm segments, two with heads attached, were passed. The heads had a groove on the side. The uterus consisted of a small rosette body near the centre, which would stamp it as a *D latum*. See Fig 8.

Dog No 4 was fed on larvae infected pike from Lake Manitoba. Four weeks later ova, typical of *D latum* were found in his stool and a vermifuge the following week caused six whole worms

FIG 8—Segments of fish tapeworm ($\times 5$) cleared in methyl salicylate to show the central uterus. From dog No 3.

and two without heads to be expelled. Microscopical examination of the heads and segments showed them to be typical *D latum*.

PREVENTION OF HUMAN INFECTION

It is impossible to inspect and exclude infected fish for sale in the same manner as meats. The health authorities should warn the public by announcements about species of fish known to be infected. Freezing, smoking, dry cleaning, or pickling in salt does not destroy the parasite. If eaten, these fish should be thoroughly cooked. Five minutes at 65 degrees C will kill the larvae, and for ordinary cooking the temperature reaches 100 degrees for as long as ten minutes. A possibility of infection remains in some of the quick service restaurants where the cooking may not be sufficiently long to kill any deeply embedded larvae.

While thorough cooking renders all fish safe, we do not like to eat fish containing larvae any more than we like to eat measly meat. We should therefore devise means of breaking the life cycle of the *Dipyllobothrium latum* at some point.

I am indebted to Dr Wm Boyd, Professor of Pathology, for the many valuable suggestions he has given me in this work.

SUMMARY

1 Most valuable in the diagnosis of fish-tape worm infection is it to find out about (a) The eating of fish likely to be infected, (b) Carelessness with regard to cooking, (c) The passing of segments by the bowel, (d) Examination for ova by a concentration method

2 Anæmia may be slight or of the severe aplastic type. It only occurs in a small percentage of infected cases, and is usually associated with degeneration of segments, so that none may be passed, though many ova will be

3 The infection is commonest in people who come from the Baltic provinces, especially Finland and Russia, where eating uncooked fish is a common habit. Among the Jews, only the women get the infection because they taste the fish in preparing it for cooking

4 The Winnipeg General Hospital records show 5 cases in 1927, 10 cases in 1924-26. Many

diagnoses of tapeworm are made without stating the variety. Most tapeworm infections are treated out of hospital

5 Seven out of thirty-five pike examined, from Lake Winnipeg and Lake Manitoba, were infected with fish-tapeworm larvæ, as shown by feeding the larvæ to dogs. Two out of seven pickerel were similarly infected. Examination of gold eye, sucker, tullibee, herring and white fish revealed no larvæ in the flesh or viscera

6 Thorough cooking of fish is the most important immediate means of preventing human infection

ANEURYSM DUE TO TUBERCULOSIS WITH THE REPORT OF A CASE OF TUBERCULOUS ANEURYSM OF THE RIGHT FEMORAL ARTERY*

By R. B. MALCOLM, M. S. C., M. D.,

Montreal

THE production of aneurysm of the large arteries by various infective processes has always been of interest to pathologists, and particularly those caused by the tubercle bacillus. Such aneurysms may arise either by direct extension from without, or from within, by involvement of the intima on the one hand or by "mycotic embolic thrombosis" on the other.

Eppinger¹ states, "By a mycotic embolic thrombosis (i.e., in one of the vasa vasorum) there occurs an acute peri- and mesarteritis, leading to complete solution of continuity of the elastica and damage to the resistant remaining tissue (e.g., adventitia) to form an aneurysm." He insists upon the multiplicity of the lesions within a small radius as constituting the strongest evidence of its embolic or thrombotic origin.

As early as 1844, Rokitsky² noted the

relationship of a mycotic abscess to the production of an aneurysm caused by the bursting of an intraparietal abscess into the lumen of the aorta, but the first record of the production of an aneurysm through tuberculosis was by Kamen,³ who described in 1895 the case of a soldier, twenty-four years of age, who had chronic pulmonary tuberculosis and acute milary tuberculosis, the former caused an aneurysm of the ascending portion of the aorta just above the aortic cusps, by direct extension from caseous mediastinal glands.

In 1896 Hannau and Sigg⁴ reported a case of an aneurysm of the thoracic aorta, arising in connection with a tuberculous lung cavity. The entire wall became replaced by tuberculous tissue. The cavity was filled with a caseating mass of thrombotic material. Tuberculosis, secondary to other degenerative changes in the aorta and causing marked weakness of the wall has been reported by Huchind and Mouget⁵ in 1904, by Nattan and Larrier⁶ in

* From the Surgical Service of Dr. E. M. Elberts and the Pathological Department of the Montreal General Hospital.

1899 and two similar cases are reported by d'Amblaid⁷ in 1906 and 1905

Pel¹⁰ of Amsterdam reported a case of a young girl, twenty years of age, who died from an aneurysm of the superior mesenteric and femoral arteries, undoubtedly of tuberculous origin. The autopsy showed tubercles to be present in the mitral valve. Pel considered that the vascular lesions in this case were due to tuberculous emboli from the mitral valve.

Tozer⁹ reported a tuberculous aneurysm of the abdominal aorta which ruptured into the duodenum. In the media, which was very much thinned out, the elastic tissue was replaced by fibrous tissue filled with lymphocytes. The intima showed tuberculous granulations with numerous giant cells.

In 1910, Ribbert demonstrated a specimen from a woman, forty-six years of age who died of chronic pulmonary tuberculosis, in whom communication had been established between the lumen of the aorta and a cavity lying in a large tuberculous mass, which arose from the periosteum of the vertebrae. The outer layers of the aorta had been destroyed and replaced by tuberculous tissue, and the process had advanced until the rupture of the intima had occurred. A small oblique tear of the intima opened into a short canal which led from the aorta into the cavity. The cavity itself was nearly filled with caseous clot. As he pointed out, this was not a true aneurysm though the circulating blood passed in and out of the sac.

In 1913 Samuel R. Haythorn⁹ reported a case of "Tuberculous Aneurysm, involving the Right Common Iliac Artery." The patient was a male aged thirty-three. The clinical diagnosis was general military tuberculosis, chronic pulmonary and right-sided renal tuberculosis, tuberculous enteritis, and aortic aneurysm. At necropsy an aneurysm of the right common iliac artery was found, measuring 7 cm. in length, 4 cm. in breadth and 3 cm. in thickness. Its wall appeared to be continuous with the common iliac above and with the internal iliac below. When the vessels were opened, the aneurysm was found to involve the common iliac only. The interior of the sac was almost filled with reddish-grey thrombotic material, which appeared caseous. Microscopically, the outer wall of the sac was found to be continuous with the adventitia of

the common iliac above and with that of the internal iliac below. The media and intima took no part in the enlargement. Great numbers of acid-fast bacilli were found diffusely distributed throughout the entire contents of the sac. Acid-fast bacilli were found in the glomerular capillaries of the kidneys, as were also many tubercles throughout the renal substance. Acid-fast bacilli were also found in the lungs. Tubercles were seen in the spleen and liver. Haythorn believed, in this case, that the tuberculous process spread directly to the adventitia of the right common iliac artery from some adjacent focus, that it so involved the media as to lead to rupture, that the pressure of the blood pouring through the opening separated the inner layers of the media from the outer layers and from the adventitia, thus producing a dissecting aneurysm, that the blood in the sac thus formed underwent coagulation, and became infected from the tuberculous adventitia, and thus served as a medium for the growth of the tubercle bacilli and as a source of constant supply of them to the blood.

In 1918, Lutembacher¹⁰ published two cases of aneurysm involving the auricular appendages of the heart, which were proved to be tuberculous. In 1921, Pistaechi¹⁰ reported a case of tuberculous granulomata of the aorta. In 1922, Apeit and Bordet¹⁰ showed, before the Anatomical Society of Paris a small aneurysm of the arch of the aorta in a case of tuberculous broncho-pneumonia. Search for bacilli in the sections was negative, but giant cells were found. The authors concluded that this lesion was due to tuberculosis. In 1922, Le Noble, who gives the previous references, himself reported a case of aneurysm of the first portion of the aorta, undoubtedly of tuberculous origin.

In 1925 W. A. Dafoe¹¹ reported two cases of ruptured aneurysm of the abdominal aorta, due to tuberculosis. In the first case he considered that the rupture of the aorta was due to the spreading of the tuberculous process to its adventitia and media from the attached tuberculous lymph-nodes. In the second case the tubercles in the organs were all of fairly recent origin. E. P. Blockman¹¹ reported a case of aneurysm of the femoral artery in a boy, fourteen years of age, with tuberculosis of the spine. Examination showed the presence of a diffuse pulsating mass in the region

of the femoral artery. A thrill was present and a systolic murmur was heard over the tumour. Pressure above caused diminution of the mass. By operation the aneurysm was removed. Areas of caseation were found. Giant cells were present in the wall, but no acid-fast bacilli were found.

In March, 1928, W. P. Thomson¹³ reported a case of aneurysm of the hepatic artery, apparently caused by invasion of the arterial wall from an adjacent tuberculous focus. This case was a male, aged forty-three, who had had a tuberculous infection of the pubic bone ten years previously. In November, 1926, he was admitted to the Johns Hopkins Hospital with clinical signs pointing to gall-bladder disease. Ten days later, operation showed a large oedematous gall bladder containing blood clot and blood stained bile. No stones were present and the gall bladder was drained. Eighteen days after admission the patient died in coma. The necropsy showed an aneurysm of the hepatic artery. In the common duct there was a thrombus-like mass just above the entrance of the cystic duct. This mass surrounded a tear in the wall of the common duct, 2.5 cm. in length, though there was direct communication with a small aneurysm of a branch of the hepatic artery. Sections showed rupture of the wall of the artery surrounded by a tuberculous mass which contained scattered epithelial cells and giant cells. No tubercle bacilli were found.

REPORT OF CASE

Male, aged 72 years, admitted to the Montreal General Hospital on December 29, 1926.

Complaints—Pain and swelling of the right thigh.

Personal History—He had followed the sea most of his life, latterly as captain of a sailing vessel, had been exposed to all kinds of weather, but had had no serious illness. About three years ago he first noticed a lump in the left groin. This was an indirect inguinal hernia for which he has since worn a truss continuously.

Present Illness—The patient was first seen by the writer on December 15, 1926, at which time he complained of much pain in the region of the inner aspect of the right knee. Examination at that time revealed no evidence of any swelling of the knee or extension into the joint.

This pain persisted for about five or six days, and was then followed by severe pain on the inner aspect of the thigh, a few inches below Poupart's ligament. The femoral artery was palpable over this mass, but did not seem to be involved in it.

He was admitted to the Montreal General Hospital on December 29, 1926. On admission the whole right leg was larger than the left, the most marked swelling being just below Poupart's ligament and in the upper third of the thigh. The circumference of the limb at the level of the great trochanter was 24 inches left thigh, 17 inches, right calf, 15¾ inches, left, 14 inches, right ankle, 9¼ inches, left, 9 inches. The swelling was bounded above by Poupart's ligament, and below it shaded off gradually into the general contour of the thigh. On auscultation of the tumour, a to-and-fro murmur was heard just below the mid-portion of Poupart's ligament. The whole internal aspect of the thigh was ecchymotic in the upper third.

While in hospital the patient became dull and listless, seeming to lose his memory, and losing all realization of time and place. On January 6th there was an attack of blowing breathing over the lower lobe of the left lung and many large rhonchi and fine moist râles were heard. The heart was not enlarged to percussion but was very difficult to hear, no murmur heard. The pulse was irregular and showed extra systoles. On January 7th signs of pneumonia developed over both lower lobes. On January 8th the patient died.

Laboratory findings were as follows. The Wassermann reaction was negative. Red blood cells 3,440,000, white blood cells 9,000, haemoglobin 70 per cent, the urine showed no albumen and no casts, the blood urea nitrogen was 42 mgm., creatinine 1.47, sugar 0.137.

The clinical diagnosis was aneurysm of the right femoral artery, and broncho-pneumonia.

A summary of the findings at autopsy is as follows. (A 27-11.) Pathological Diagnosis: ruptured femoral aneurysm (right) (tuberculous aortitis), haemorrhage about right femoral artery, minimal tuberculosis of the lung, liver, spleen, pancreas, prostate and adrenals, multiple acute duodenal ulcers (four), chronic fibrous pleuritis, thrombosis of femoral vein and its tributaries below an

aneurysm of the right femoral, bronchopneumonia of the right and left lungs

A swelling of the right thigh was found to be caused by free hæmorrhages into the soft tissues and muscles surrounding a ruptured aneurysm of the femoral artery. The aneurysmal dilatation of the femoral artery began 17 cm from the bifurcation of the aorta. It was 6 cm in length and fusiform in shape. The aorta and iliac and femoral arteries showed considerable atheroma, ulceration and calcification. The femoral vein was collapsed above

the aneurysm, but dilated and thrombosed below it. The whole tumour mass, which was oval-shaped, consisted of the femoral artery and vein, the saphenous vein and tributary branches, the psoas, the rectus femoris, the pectineus and the adductor longus, measured about 4 cm in diameter and 20 cm in length. The surrounding muscles were friable and necrotic, owing to the extensive infiltration with free blood and pressure upon their fibres. The fascia lata directed the free blood anteriorly and medially. The aneurysm was just proximal to the origin of the profunda femoris artery. The deep tributaries of the femoral

FIG 1—Drawing of gross specimen to show (a) Aneurysm, (b) Thrombosed femoral vein, (c) Extravasation of blood into surrounding tissue, (d) Orifice of aneurysm. Outline of bony structure shows anatomical relations.

FIG 2—Section of lung showing the presence of giant cells.

FIG 3—Section of spleen, showing large giant cell.

FIG 4—Section of liver, showing tuberculous area with large vacuolated giant cell.

vein which lie deep to the artery at this point were thrombosed. The femoral artery and vein were laid open. There was considerable atheroma and calcification of the femoral artery, and the aneurysm was found to communicate posteriorly and medially with the surrounding tissues. No communication could be traced with the femoral vein, which was occluded by pressure of the aneurysm and the surrounding infiltrated tissues and was thrombosed distal to the aneurysm. The escaped blood was held partly between the fibres of the

muscles themselves and partly by their fasciæ, which prevented it, anteriorly, from extravasating more freely into the subcutaneous tissues.

MICROSCOPICAL EXAMINATION

Heart—Endocardium appeared normal.

Lungs—The bronchi contained an inflammatory exudate and were surrounded by a thin zone of inflammatory cell infiltration. Some of them had beside them areas with giant cells and connective-tissue proliferation.

Giant cells were found in the spleen, liver,

FIG 5—Section showing presence of caseous tuberculous area in media of vessel wall

FIG 7—Section through media of vessel wall, stained for *B. tuberculosis*. Note the great number of organisms, singly and in clumps.

FIG 6—Section showing giant cell in media of vessel wall

pancreas, adrenals, and prostate. None were found in the kidneys.

Report on the femoral aneurysm: "The vessels of the adventitia are engorged. There is extensive necrosis of all coats with slight fibrous connective-tissue proliferation. Giant cells observed. Suitable staining methods reveal the presence of many acid-fast bacilli in the media. These organisms conform to the size, shape and staining reactions of the tubercle bacillus."

SUMMARY

To date twenty cases of aneurysm due to tuberculosis have been reported. In only two of these has *B. tuberculosis* been isolated. In Hawthorn's case *B. tuberculosis* was found in the caseous clot filling the aneurysmal sac. In the present case *B. tuberculosis* has been found in

the media of the arterial wall, showing the infection to have been due to transmission of the disease through the vasa vasorum

THE DEATH-ROLL OF APPENDICITIS DUE TO THE ABSENCE OF CLASSICAL SYMPTOMS*

BY HERBERT A. BRUCE, M.D., F.R.C.S. (ENG.),

*Professor of Clinical Surgery, University of Toronto,
Consulting Surgeon, Toronto General Hospital*

UNTIL within the last year or so I was under the impression that appendicitis was so well understood by the profession that further discussion of the subject before a medical gathering was unnecessary. I have had a rude awakening, due to meeting with far too many cases unrecognized at an early stage, when operation would have been safe and simple, but, left until grave complications had set in, making operation almost, if not quite, futile. The blame for this cannot always be placed upon the family physician, because often he has not been sent for until too late for early operation.¹ Dr W. E. Gallie states that in 70 per cent of the cases admitted into the Children's Hospital, the appendices had already ruptured. In these cases the parents are almost entirely to blame, because as a rule they have given the child castor oil, and have not called the family doctor until the appendix had ruptured. In these days when the public is so well informed on medical subjects, it is becoming increasingly difficult to explain to them why their loved one was not operated upon at an earlier date, when recovery could have been expected, unless it is pointed out that the cause rests with themselves.

Before entering upon the subject proper of the paper, I should like to make a few further

remarks. It seems hardly credible that only so recently as to be within the professional memory of many of us here, the various pathological phenomena in the right iliac fossa have been shown to have their origin in the vermiform appendix.

Celsus,² who lived in the early part of the first century of our era, speaks of the "iliac and colic passion," which terms were used until well toward the end of the eighteenth century, to describe a condition which we now know to have been due to appendicitis. Peter³ Lowe, writing in 1612, gives the interesting information, on the authority of Lonicus, that "Hippocrates did die of this disease."

Kronle⁴ appears to have been the first to remove an appendix for acute disease in 1884. In 1887 Sands⁵ successfully closed a perforation of the appendix by suture while in 1888 Tieves⁶ did a laparotomy for relapsing typhlitis, and found the omentum adherent to the appendix, which was thus kinked. Tieves therefore cut the adhesion, sutured a tear in the peritoneum, bared the convex surface of the appendix of its peritoneal coat, thinking it would thus contract new adhesions with the parietal peritoneum on its outer side, and so be held straight, and closed the abdominal wound, leaving the appendix in its new position. Recovery ensued, but how fantastic the procedure seems to us to-day. Being en-

* Read before the Academy of Medicine, Toronto, November 15, 1927

comaged by his experiences, he next removed the appendix for recurrent attacks, which was the first time that the operation was performed in the interval.

In 1886 Reginald H. Fitz¹ pointed out that in 209 cases of typhlitis or perityphlitis, the symptoms were identical with those observed in 257 cases of perforation of the appendix, which helped to convince the medical world that practically all inflammations in the right iliac region are due to appendicitis. McBurney,² in 1890 described the area of tenderness which bears his name. In the same year Nicholas Senn³ pointed out that affections of the appendix were bacterial in origin.

During my year as house surgeon in the old Toronto General Hospital, 1892-1893, I can only remember one case of appendicitis being operated upon and then it was considered such an unusual and important event that the entire surgical staff was present, three senior surgeons actually taking part in the operation. At this period we were still constantly hearing cases described as typhlitis and perityphlitis. In the main, leeches were used to combat the disease or when the disease had thoroughly "ripened" by incised poulticing, the abscess either opened spontaneously or the skin was incised to let out the pus. From 1894-1897 while attending the London hospitals, I saw but few cases of appendicitis operated upon.

Many years were spent in discussion as to whether appendicitis was a medical or a surgical disease. Then, when it became definitely recognized as a surgical disease, there was a prolonged period of discussion as to the proper time at which to operate. Ultimately this was settled and now all surgeons are in agreement that the best time to operate is as soon as possible after the beginning of an acute attack the earlier the better. If done within the first twelve or twenty-four hours the mortality will be little greater than in the case of an interval operation. May I here express my strong conviction that, in doubt about the diagnosis but with reasonable cause for believing that it is a case of acute appendicitis, then give the patient the benefit of the doubt by having the appendix removed. I am sure the risk of the operation is much less than the risk of allowing the disease to progress. Better to remove a dozen appendices not diseased than

to leave one which will progress to diffuse peritonitis.

I should like now to report three or four typical cases.

CASE 1

A boy, G. W., aged ten, was taken ill on Christmas night with slight mid-gastric pain and vomiting, but thought by his physician to be due to over-eating. He had *no rigidity*. He was somewhat better the next day and had a *normal temperature* and normal pulse rate. On the third day the pain and vomiting returned and continued for forty-eight hours, when his temperature reached 104°, with a pulse rate of 140, but still *no rigidity*. The leukocyte count was 12,000, 88 per cent polymorphonuclears. I then saw that patient for the first time, that is five days after the beginning of the attack, and although there was *no rigidity* to be made out there was slight tenderness on pressure, and I diagnosed diffuse septic peritonitis, due to a ruptured appendix, which was confirmed at operation and found to be of streptococcal origin. He developed cellulitis of the anterior abdominal wall, a subphrenic abscess, and empyema of the right pleural cavity. Although prompt measures were taken to deal with these complications, he finally succumbed.

CASE 2

Mr. S. P., aged 58. He was taken ill with indefinite pain in the abdomen, *but no vomiting*. He had a cough and some rales at the base of his lungs. During the next two days he had pain in the abdomen and distension, but *no special rigidity*, and his physician diagnosed it as influenza and attributed the pain in his abdomen to pleurisy. When I saw him on the evening of the fourth day of his illness, his pulse was 124, his temperature 100°, and the abdomen was greatly distended and of board-like hardness. A diagnosis of diffuse peritonitis, due to a perforated gangrenous appendix was made, and the physician and friends told that an operation offered such a very slight chance that I did not advise it. However, I ultimately yielded to their pleadings that he be given a chance, even though it was only one in a thousand. At the operation the peritoneal cavity was found filled with foul-smelling pus; the intestines were glued together and deep red in colour and the appendix was gangrenous. He died two days later of septicæmia and obstruction.

CASE 3

A girl, H. O., aged nine, taken ill in the evening, with pain in the abdomen and vomiting. The physician who was called could find *no rigidity* and as the temperature and pulse were both normal, attributed the condition to something she had eaten. As she vomited all the next day, and in the evening her temperature went up to 100° with a pulse of 100 she was brought into the hospital where I saw her. The leukocyte count was 18,000 with 92 per cent polymorphonuclears. There was still *no rigidity*, but a diagnosis of diffuse peritonitis was made. At the operation the appendix was found lying in the pelvis with pus throughout the abdomen of pneumococcal origin. The patient developed intestinal obstruction, acute dilatation of the stomach and ultimately died of septic pneumonia.

I could go on repeating such cases in considerable numbers, but think these are enough to indicate the obvious lesson to which they point. I should like however to refer briefly to another case which does not strictly belong

to the title of the paper, but which furnishes an excellent warning to the public

CASE 4

J C, aged 8, was taken ill with pain in the abdomen and vomiting, the illness continuing for three days without improvement, during which time he was treated by his mother with castor oil and enemata, she thinking that the trouble was due to something he had eaten. The boy himself asked his mother to call a doctor on the third morning, when the latter sent him into the hospital and I operated immediately upon admission and found a ruptured gangrenous appendix, with diffuse peritonitis, due to the streptococcus. He developed intestinal obstruction, acute dilatation of the stomach, and died on the third day.

This case adds another to the long list of fatalities due to castor oil, and makes it more incumbent upon us to devise some more effective method of warning the public of the danger of giving castor oil to children who have abdominal pain. Years ago in papers upon this subject, I called attention to the danger of attributing any abdominal pain to an error in diet and made the statement that I had never seen a case of "acute indigestion" which was a popular term for even medical men to apply to grave abdominal disasters, such as acute appendicitis, perforation of the stomach, etc. Further years of experience have not caused me to change my opinion, but only to confirm it. Every other avenue should be thoroughly explored as a possible cause of the trouble before falling back upon a "symptom," which so-called acute indigestion usually is, and exalting it into the importance of a disease.

The delay in calling a surgeon has often been explained as due to the fact that the patient was afraid of an operation and wanted everything else tried first. It seems to me that if physicians would only acquire the habit of calling surgeons in at the outset of an acute abdominal condition, to help them make a diagnosis, a great step in advance would be made and many lives would be saved. Let the patient and friends know that the surgeon is not being called necessarily for the purpose of performing an operation, but simply because he is the best qualified man to make a diagnosis. Many times he would not operate, but he would have the opportunity of seeing surgical diseases at a much earlier stage, when the patient's chances of recovery by operation would be infinitely greater. I have no hesitation in expressing the opinion that a surgeon

with a large experience in abdominal work is much more competent to make a diagnosis in an abdominal case than is a physician, and that he should therefore largely replace the latter in consulting work in abdominal cases. The attending physician assumes a grave responsibility when he sees a patient at the onset of an acute abdominal disease, as it is upon his diagnostic acumen that the fate of that individual often depends. If he is a wise man he will ask a surgeon at once to share that responsibility with him.

Parents and relatives are only too ready to find something unusual in a "meal" to explain the illness, and it behoves the physician not to fall into this trap, but to exhaust every possible investigation at his disposal to make a diagnosis, always remembering that "an error in diet" is the least likely cause of the symptoms.

The absence of classical symptoms is sometimes due to the appendix occupying an unusual position, for example, below the brim of the pelvis, attached to the bladder, on the left side, or a retro-cæcal one. In children there is sometimes no rigidity.

The diagnosis of acute forms of appendicitis usually presents little difficulty. The sequence of the symptoms is most important, first pain, then vomiting, then tenderness over the appendix, later rigidity, and finally fever. Of these classical symptoms, the presence of fever is the least important. Vomiting may not have occurred but if not, there will usually be nausea or a disinclination for food. Tenderness, accompanied by rigidity, is the most constant and reliable sign of the disease. However, in the case of children rigidity is frequently absent, which makes diagnosis often difficult. A leucocytosis of 14,000 or 15,000, with a high polymorphonuclear count of 80 per cent, or more, usually means that the disease has advanced to suppuration, or at least to a very acute stage. At the outset, there is no means of telling whether the attack will be mild and subside spontaneously, or whether it will proceed to abscess formation or diffuse peritonitis. Under these circumstances, the only safe position to take is to advise immediate operation, unless there be some complication which would make operation hazardous.

In the treatment of paresis of the bowel,

there are two agents of great value, namely the administration of saline intravenously, and the use of the stomach and duodenal tubes. In these cases I have had excellent results following the administration of 30 cc of 30 per cent solution of sodium chloride intravenously. This can be repeated if necessary, several times.

The surgical staff of the Sick Children's Hospital, Toronto, have devised an ingenious apparatus for the intravenous administration of salt solution, either isotonic or hypertonic. The apparatus used consists of a burette connected by a short piece of rubber tubing to a perforated rubber stopper. In the lower end of this is an adapter which is commonly used on a 30 cc syringe. The rubber stopper feeds into the barrel of a 20 cc record syringe. Attached to the lower part of this is a rubber tube connected with a gold needle which is placed in the vein. A very simple dressing keeps the needle in place and the rate of flow is regulated by a pinch cock above the syringe. The ordinary Murphy drip as used by Matas¹⁰ was found to fill up under too little pressure and discontinue the flow. In a small percentage of cases thrombosis of the vein complicates this procedure. This method serves two purposes, it supplies the patient with fluid and also replaces his diminishing chlorides. Glucose can be added

The second agent, repeated lavage of the stomach, is a life saver. In many cases, to spare the patient the discomfort of passing the larger tube, he is induced to swallow a duodenal tube, the upper end of which is fastened to his cheek. Through this, one can withdraw the contents of the upper intestine and administer fluids. This can be left *in situ* for many days without causing the patient any discomfort. A word of caution in regard to its prolonged use is indicated, as one must make sure that the patient is receiving a sufficient supply of sodium chloride. I have seen two cases of tetany develop while using a duodenal tube, which I thought were due to depletion of chlorides, through removal of the gastric juices. The cases recovered after the removal of the duodenal tube.

Diphyllobothrium Latum in Massachusetts—L. G. McGavran and M. Songkla, Boston, report two indigenous cases in Massachusetts. The first patient, a boy, aged 3 years 2 months, of native Russian Jewish parentage, began to pass "white strips" about five months before admission which were identified by the family physician as "tapeworms". The diagnosis of *Diphyllobothrium latum* was made later on the finding of numerous typical eggs in a simple smear examination. Further questioning elicited the fact that the patient was very fond of fish and had been caught stealing and eating bits of raw fish while his mother prepared a meal. Physical examination was essentially negative. The other patient, a girl, aged 4 years 2 months, was born in Greater Boston and had lived in Chelsea, Mass., all her life. The father was born in Russia, the mother in Boston, both were of Jewish parentage. The patient passed a 20 foot long yellowish white, ribbon like worm. No head was found. There were no symptoms, and the patient was well all the time. The worm was diagnosed as *Diphyllobothrium latum*, but the specimen unfortunately was not preserved. On the next visit, eggs of the same organism and segments were found and were identified as *D. latum*. Further history revealed that the family

had fish twice a week, usually fried and occasionally as fish balls. The mother did not remember that the patient had her meals anywhere except at home. She had noticed that the patient was in the habit of picking up and putting into her mouth bits of raw hamburger steak while she cooked the family meal. She had not observed the child picking up any raw fish but would not exclude the possibility. Physical examination showed that the child was very well developed and well nourished and entirely normal. Inquiries made at fish markets showed that the chief wholesale supply of fresh water fish comes from the Great Lakes region and the Ohio river. Therefore, the fresh water fish apparently responsible are either white fish, *Coregonus clupeaformis*, lake herrings, *Leucichthys*, carp suckers, *Carpoides thompsoni*, suckers, *Catostomus commersoni*, the common pike, *Esox lucius*, and the yellow perch, *Perca flavescens*, all of which are shipped in large quantities out of the Great Lakes region to eastern markets. Because the sewage of so many towns empties directly into the Great Lakes or other bodies of fresh water, the fish of these regions have every opportunity of becoming infected and must be considered as the probable source of infection.—*J Am M Ass*, May 19, 1928, 1607

VERTIGO OF UNKNOWN ORIGIN, OCCURRING AS A MILD EPIDEMIC

By C B Ross, B A, M D, C M,

Sanitarium, Ont

IN the wards of the Muskoka Hospital for Consumptives have been observed several cases which present evidence of functional disturbance of the vestibular portion of the eighth nerve or of the labyrinth, without the accompanying auditory symptoms usually found in Menière's disease

Among the symptoms present, vertigo plays the most prominent part. This is usually severe, especially when the patient is moving and in the upright position. It may be so intense as to cause the patient to stagger in walking, or even to collapse. Even in the recumbent position the vertigo may be very marked, especially on lateral rotation of the head. When the patient lies on his back, the head is frequently held rigidly in one position, usually facing directly anteriorly or slightly to one side, and the information will be volunteered that movement of the head laterally brings on a wave of giddy sickness.

Nausea is always present to some degree, and usually vomiting. Both these symptoms vary considerably in intensity. They appear after the onset of the giddiness, are apparently secondary to it, and disappear before that symptom is entirely gone. When first seen, the nausea and vomiting may be so severe as to make the observer suspect an abdominal catastrophe. Usually, however, the patient gives of his own accord a description of the giddiness, which will always be found to have preceded the gastric symptoms.

Severe headache is usually absent. Sometimes, on being questioned, the patient will state that headache is present, but the usual complaint is of a vague distress, a "heavy" or "dull" sensation behind one or both ears, usually worse on one side. When present, this sensation is most frequently on the side on which, on turning the head, the vertigo is most markedly increased.

Nystagmus is present in most cases and it is variable in type and degree.

Auditory disturbances are never observed.

One patient showed a scarred and retracted ear-drum from a recently incised and healed acute otitis media. Two others gave signs of a mild chronic catarrhal condition of the middle ear. In none of the cases were auditory disturbances found, nor any evidence which would suggest the presence of an active infective process of the middle ear.

A slight range of fever occurred in only three of the cases, lasting two or three days at the most, and only in one did it rise to more than 100 degrees.

The syndrome was first observed in a young man who was suffering from minimal pulmonary tuberculosis, complicated by spinal caries and psoas abscess. Tuberculous meningitis was first suspected, for, though the onset was not typical of this fatal complication, it frequently happens that tuberculous meningitis does not follow in its inception the classical text-book picture. The further evolution of the syndrome, however, satisfactorily ruled out the possibility of tuberculous cephalic or meningeal disease. The majority of the afflicted patients were those who were closely confined to bed because of complications, or because of the advanced extent or activity of their pulmonary lesions. It was thought at first that this constant recumbency might have been a congestive factor in the etiology of the disturbance, but in the last cases to come under observation this possibility seems rather remote.

One might suggest the possibility of the symptoms being due to a toxic neuritis, of a tuberculous nature, of the vestibular portion of the eighth nerve, or to a toxic inflammation of its highly specialized appendage. However, previous experience with tuberculosis has not shown similar cases.

The phenomena roughly shape themselves into a form which suggests an inflammatory disease of infectious origin which, so far as can be found, has not previously been classified. The thought occurred that the appearance of

the syndrome might be part of a mild contagion, protean in its symptomatology, and manifesting itself in other cases in a less characteristic way. But a fairly careful examination of the other patients and residents for local neuritis, myalgia, or general symptoms of obscure infection, has failed to reveal any corresponding increase in the occurrence of these.

The cases on record at the Muskoka Hospital are listed as follows —

CASE 1

H. R., male, aged 22. Minimal pulmonary tuberculosis, spinal tuberculosis with pons abscess, immobilized on a Whitman spinal frame.

July 23, 1925, vertigo commenced suddenly and severely, with nausea and severe vomiting. The least movement of the head laterally from the dorsal position served to precipitate an attack of dizziness, nausea and retching. Movements of the head to the left caused more disturbance than to the right. A vague distress was complained of behind the left ear. There was a moderate degree of lateral nystagmus. The condition remained severe for three days and then gradually disappeared, the gastric symptoms disappeared first, and slight dizziness remained until about ten days after the onset. There was no fever at any time. There were no auditory disturbances nor abnormal findings in the ears. There have been no recurrences. Present condition well and working.

CASE 2

R. M., female, aged 32. Minimal pulmonary tuberculosis.

January 17, 1927, vertigo commenced suddenly. She staggered and almost collapsed on attempting to walk. Nausea and vomiting were severe, the latter lasting for four days, and the nausea slightly longer. There was severe headache in the vertical region, and a sense of fullness behind the right ear. Attacks of vertigo were precipitated on lateral rotation of the head, particularly to the right. Twelve days after the onset there was still some dizziness, without nausea or vomiting. At this time there was a slight degree of past pointing, nystagmus, rotary in type, looking to right and left, was present but not marked, and the patient could walk on a straight line. Both eardrums were normal and there were no auditory disturbances. There have been no recurrences. Present condition well and working.

CASE 3

M. M., female, aged 41. Advanced pulmonary tuberculosis, intestinal tuberculosis.

February 7, 1927, developed a moderate amount of dizziness, worse on turning head laterally, particularly to right. She was nauseated and vomited. There was no vomiting after the first day, but the dizziness and, to a lesser extent, the nausea, persisted for six days and recurred occasionally for another ten days. Lateral nystagmus was present and fairly well marked. There was no pain nor distress in the head other than the vertigo. There were no auditory symptoms and the ears were normal. There was a rise of fever to 100 degrees from a previous range of slightly above 99 degrees, which persisted with daily remissions for five days, but such exacerbations of temperature were not unusual in this patient. She died from tuberculosis, August 6, 1927.

CASE 4

M. M., female, aged 39. Advanced pulmonary tuberculosis.

May 19, 1927, she became dizzy on turning the head to either side, particularly to the right. She was nauseated and vomited several times during the day. Nausea and vertigo persisted with diminishing intensity for about a week. Nystagmus was present during the first three days to a moderate degree (lateral type). There was headache and a vague distress behind the right ear. At no time was fever present. There have been no recurrences. Present condition tuberculosis unimproved.

CASE 5

D. C., male, aged 29. Moderately advanced pulmonary tuberculosis, tuberculosis of spine and epididymus, is wearing a spinal brace after having been successfully treated by immobilization on a Whitman spinal frame.

On August 6, 1927, he became dizzy and nauseated and vomited two or three times. Lateral rotation of the head brought on the dizziness. There was lateral nystagmus on turning the eyes either way. There was no headache, nor other distress in the head, save the vertigo which gradually disappeared in about one week. There was no rise of temperature. Two months later, October 3, 1927, he had a similar attack, disappearing gradually in about two weeks, and five months later, March 5, 1928, the symptoms reappeared less severely for three days. There have been no auditory disturbances, both ear drums appear to be somewhat retracted with loss of lustre. Present condition tuberculosis, pulmonary disease and tuberculous complications are quiescent.

CASE 6

F. C., female, aged 17. Minimal pulmonary tuberculosis.

On September 25, 1927, she was seized suddenly with vertigo, nausea and severe vomiting. The latter disappeared in twenty-four hours, but slight nausea and considerable vertigo persisted for two more days. The patient staggered on attempting to walk the first day. The dizziness was brought on by lateral rotation of the head, most marked to the left. Nystagmus was not noticed. All symptoms disappeared within four days. One month previous to the attack the patient had complained of an intense pain behind the right ear, involving the pinna, the mastoid area, and part of the lateral scalp, which from its nature and distribution was considered to be a neuritis. This has recurred once, four months after the attack of vertigo. There were no auditory symptoms. The patient had a history of a right-sided otitis media some weeks before, but examination showed a slightly retracted drum with the incision well healed and the ear was otherwise apparently normal. The temperature was slightly elevated for four days. There have been no recurrences of vertigo. Present condition tuberculosis improved.

CASE 7

I. R., female, aged 22. Moderately advanced pulmonary tuberculosis, tuberculosis of the right sacroiliac joint with abscess, simple goitre, immobilized in a plaster cast.

October 17, 1927, was seized suddenly with vertigo, followed by nausea and vomiting. Lateral rotation of the head precipitated the attacks, particularly on turning to the right. There was no pain in the head, but a sense of dullness behind the right ear was described. She vomited frequently for two days, and the vertigo and, to a lesser extent, the nausea, persisted for nine or ten days. Nystagmus was moderate and inconstant. There was no fever at any time. Both ear drums were

normal in appearance and there were no auditory disturbances. There have been occasional recurrences of slight vertigo on turning the head to the right, but these have never lasted more than one day, and have been without any noticeable etiological factor. Present condition: sacro iliac disease considered well healed, pulmonary disease, apparently arrested.

CASE 8

A F, female, aged 30. Advanced pulmonary tuberculosis, right sided hydrothorax, following spontaneous pneumothorax, tuberculosis of the right sacro iliac joint, immobilized on a Whitman spinal frame.

October 23, 1927, was seized with severe dizziness and headache. The vertigo was induced by turning the head either to right or left, but particularly to the right. There was slight nausea but no vomiting. A vague distress behind the right ear was described. The dizziness was marked for four or five days, and there have been frequent recurrences. There was a slight degree of past pointing. Nystagmus was inconstant, usually most marked on turning the eyes to the right with the rapid phase to the left. There were no auditory disturbances. The right drum was retracted with other evidence of a mild chronic catarrhal condition. There was no fever. Present condition: tuberculosis generally improved, still having occasional recurrence of vertigo.

CASE 9

R A, female, aged 24. Minimal pulmonary tuberculosis.

On March 3, 1928, vertigo commenced, followed by nausea and vomiting. She staggered when she walked and almost collapsed. The vomiting was particularly severe on the second day and diminished in intensity on the third. Vertigo and nausea persisted, the former to some degree for nine days. Nystagmus was not sufficiently marked to be recorded. There was no fever throughout the attack, and there have been no recurrences. Present condition, tuberculosis, improved.

To this list may be added the non-recorded occurrence of similar phenomena in three members of the professional or employees' staff

of the hospital. One of these ran a highly febrile course for several days with generalized neuritic symptoms. Another has had recurrences, diminishing in intensity, for three or four months.

M M Fisher, of Gravenhurst, reports one case of severe and unaccountable vertigo, with recurrences over a period of three months.

D W Crombie, of the Calydor Sanatorium, has observed similar phenomena in five or six of his patients, in some of whom recurrences were particularly outstanding.

As regards treatment, the severe symptoms seem to be partially controlled by bromides, luminal or atropine.

CONCLUSIONS

1 Several cases of vertigo of unknown origin are reported.

2 In none of these cases were there present any of the auditory disturbances usually found in Menière's disease.

3 Definite disease of the middle ear occurred so infrequently as to be considered a negligible factor in the etiology of the disturbance.

4 The occurrence of the phenomena in so many cases suggests an infectious and contagious character.

5 The frequency of recurrences denotes that the lesion is of inflammatory nature, and that complete resolution sometimes takes place slowly.

MIMICRY OF THE ACUTE ABDOMEN IN CASES OF CYCLIC VOMITING IN CHILDREN, WITH REPORT OF A CASE

By THOMAS GIBSON, M B, C M, (EDIN), AND JOHN MANN, M D, C M,

Kingston General Hospital, Kingston

DURING the years 1923 and 1924 I observed in general practice several cases where the symptom-complex of acute appendicitis was closely simulated in the course of severe attacks of cyclical vomiting. In one of these, where I was in doubt whether appendicitis might be present as well as the recurring disease, I noticed that immediately after the child had vomited he at once relaxed, stretched out his legs, and rolled over on his side. On palpating, forthwith, over the right iliac fossa the rigidity

and tenderness one had observed were almost gone. This seemed to settle the point, as such a dramatic change could hardly have occurred in the presence of acute inflammation of the appendix. The same symptoms recurred in the course of the same child's next attack, and here I used emesis, which followed the drinking of two tumblers of water, to solve the problem once again. The same result, viz, practically complete disappearance of rigidity and tenderness followed the vomiting. In spite of this experi-

once, the parents consented some months later to the performance of an operation, advised by another practitioner, during a subsequent attack. This was quickly followed by death.

During the following winter an experienced paediatrist advised in consultation immediate operation in a very severe case of cyclic vomiting, but on witnessing the result of emesis, produced as before by the drinking of half a pint of cold water, he revised his opinion, and the child recovered from the critical phase of his illness under the use of intra peritoneal alkaline glucose injections.

The case report which follows illustrates the symptom complex noted above and the wisdom or remembering that one may make a serious or fatal error in hurrying on an operation in the presence of a severe condition of acidosis, which may itself be a sufficient explanation of the symptoms present. In the case of B. M. described below, the attack of cyclic vomiting was beginning to break up by the time he reached hospital, because the vomiting phase was nearly over and the local signs suggestive of acute appendicitis had simultaneously become much less significant.

I have been in the habit of referring to my experience in these cases in the course of therapeutic talks during the past four sessions. Dr. Mann tells me that the remembrance of these case histories at once came into his mind when B. M. arrived in hospital, so that the urine tests for acid bodies and a blood count were at once made. Both were against operation, by pointing, the one towards acidosis, and the other away from any condition accompanied by septic absorption. The use of experimental emesis was not called for here, the case having developed favourably beyond its earlier acuter phase. The signs suggestive of acute appendicitis and the stomach symptoms disappeared together.

The history tends to confirm a belief in the common occurrence of the interrelation suggested in this note, between the severe stomach

disturbance and the symptom-complex which might suggest the acute abdomen, especially in the form of acute appendicitis, in cases of cyclic vomiting.

Up to the present I have not met with any reference to the use of emesis as a means of immediate bedside diagnosis in such cases, though it is quite probable that others may have used the same manœuvre. Consequently it seemed worth while to record these observations, in order that the test may be fully put to the proof.

B. M., a boy aged five years, was sent to the Kingston General Hospital on the night of April 11, 1929, with the diagnosis of acute appendicitis requiring early operation.

On admission, the child was slightly stuporous. He complained of abdominal pain and headache. The temperature was $101^{\circ}F$. (rectal), pulse, 100, respirations, 22, leucocyte count was 7,300 per cmm. He was not vomiting, but had vomited a good deal during the afternoon before admission. He had been in perfect health until March 1st, when he had an attack of vomiting and headache. Both symptoms cleared up without treatment, and the child seemed quite well for a month.

The onset of the present attack, on April 13, was characterized by vomiting, headache, and severe abdominal pain, more marked in the right iliac region. An acute appendicitis was suspected, and the mother was advised to bring the boy to hospital.

The examination on admission revealed a perfectly soft abdomen, with no suggestion of splinting anywhere. Tenderness was not marked and the child withstood deep pressure with very little complaint. The abdomen was not distended. Examination of the chest revealed nothing abnormal.

With these negative findings, and the history of an attack of vomiting a month previously, cyclic vomiting was suspected. There was a faint odour of acetone on the child's breath. Urinalysis demonstrated the presence of acetone and diacetic acid, but was negative for sugar.

It was then fairly clear that the child had an acidosis in association with cyclic vomiting. Treatment for acidosis was started immediately. Glucose (5 per cent) with bicarbonate of soda (5 per cent) were given by the Murphy drip. The child was encouraged to drink orange juice, which he vomited at first, but after 250 cc of fluid had been given by the bowel he drank freely of orange juice and the vomiting ceased. Large amounts of fluid were then given by mouth without any trouble and the Murphy drip was discontinued. On April 15 there was only a trace of acetone and diacetic acid in the urine, and on April 16 they had disappeared. The child's condition steadily improved. By April 15 also his headache and abdominal pain had disappeared. The pulse and temperature were normal, and on April 16 he was playing with other children in the ward.

For permission to report this case we are indebted to Dr. I. G. Bogart, to whom the case was sent.

The double red cross, the internationally adopted emblem of anti-tuberculous societies, was used first by certain oriental Christian sects about the ninth century. During the Crusades, Godfrey of Bouillon, duc de

Lorraine, placed it on his standard when he took possession of Jerusalem in 1099. On his return to France it became the emblem of the House of Lorraine.

CASE 4

H. D., aged 4½ years, duration of illness, nearly three years

The kidneys were decapsulated three weeks before death. No bulging of the kidney occurred when the capsule was incised. The capsule stripped readily. Post mortem the weight of each kidney was 93 grams. These organs were slightly enlarged, brownish red in colour, much perirenal fat was present. The cortex was paler than normal and somewhat widened. A few areas of subcapsular hæmorrhage were present. The medulla was brownish red in colour and appeared to be congested. The pelvis was slightly congested. Microscopically, there was a fine fibrosis throughout the kidney, more marked in some areas. Many of the glomeruli appeared to be perfectly normal, but others were atrophied or fibrosed, and showed proliferative changes in their capsules. The tubules showed more change than the glomeruli, many were dilated and contained albumin or desquamated cells, which had in some undergone calcareous degeneration. Some contained casts. The epithelial lining cells were the seat of degenerative changes.

The liver was enlarged and somewhat fatty. The deposition of fat was more marked about the periphery of the lobules. The heart was slightly enlarged, and showed some general fibrotic change. The suprarenals were normal. The spleen was enlarged (child died of streptococcal septicæmia).

The constant findings in these four cases were the increase in the size of the kidney and the preponderance of tubular changes. Glomerular changes were practically absent in the first cases and became progressively more pronounced in the later cases. It is cases like the fourth one, with fairly marked glomerular and interstitial changes, that make one think of the possibility of these cases progressing into chronic interstitial nephritis. Kaufmann and Mason¹⁵ regard the evidence as suggestive of such a possibility, but point out that such changes as occur in the glomeruli are a result of an organizing process about degenerated cells, rather than the result of any inflammatory reaction. Dyke,¹⁶ on the other hand, studied the pathology of nephritis with œdema, and concluded that only the large white kidney found in cases having had gross hæmaturia progressed into the secondarily contracted kidney. Case 3, of the four cited above, furnishes another suggestion of the possibility of secondarily contracted kidney developing. She died more than a year after the decapsulation operation at which the piece of tissue described was obtained. Death was in part due to an infection, but true uræmia with nitrogen retention and high blood pressure were also present. Unfortunately, no post-mortem examination was permitted.

Pathological evidence of the systemic nature

of the disease is shown in the constant presence of fatty infiltration in the liver and usually in the heart. Two cases had congestion and even actual ulceration of the mucous membrane of the bowel. In view of the experiments mentioned above of the effect of adrenalectomy on the production of nephrosis, it may be of interest that in three of our cases this organ was normal, but considerably more friable than usual in the other case.

CONCLUSION

Nephrosis is in all likelihood a systemic disease, in which the kidney is secondarily affected, either by the causative toxæmia itself or by alterations in metabolism produced by the general disorder.

Its etiology is still obscure. Streptococcal infections play no part in its production. The most common organisms isolated in such cases are staphylococci, and the most frequent infectious disease from which the child has suffered is measles.

The renal changes in early cases are fairly well limited to the tubules and are degenerative in type. In more chronic cases the progressively greater involvement of glomeruli and interstitial tissue suggest the possibility that such kidneys might become secondarily contracted ones.

PRACTICAL CONSIDERATIONS IN THE SELECTION OF BLOOD SUGAR METHODS FOR CLINICAL USE IN DIABETES*

BY I. M. RABINOWITCH, M.D.,

Montreal

BLOOD sugar studies, as is well known, are now widely applied in clinical medicine, and the great majority of those making use of such data are not trained biological chemists. It is because of the latter fact that the following observations appear relevant.

The interpretation of all laboratory data used in clinical medicine depends upon a proper appreciation of the principles of the tests employed in obtaining such data. This applies particularly to conditions where two or more technical methods may be used for the same purpose, but each of which may yield different values. The estimation of the blood sugar is an example.

Those engaged for the greater part of their time in laboratory work and acquainted with current laboratory literature know that the methods of blood sugar determinations are at present, in a very unstable state. Improvements are being made continually, and for these we are indebted particularly to Professors Folin and Benedict. Unless, however, one is familiar with the reasons for the alterations of established methods, that is, unless one understands the underlying chemical and physical principles, it is a rather unsafe procedure to change routine methods which have been subjected to thorough trial or replace them by other new procedures which may appear.

In the selection of a blood sugar method there are certain important facts to bear in mind. Firstly, it is now generally recognized, though more by the biological chemist than by the clinician, that the methods commonly in use for determining the concentration of sugar in blood, yield values much greater than would be accounted for by solutions containing the same amounts of glucose in water. There are various reasons for this. One of these is that no one method is specific for glucose. What

these methods measure are reducing substances of blood, and glucose does not account for all of the latter. Since no method is specific, the selection must depend upon other considerations, the most important of which is the following: *A blood sugar test for clinical use fulfils its function only when it detects alterations in carbohydrate metabolism.* Other considerations are, the details of the preparation of reagents, stability of these, and technical details of the actual test. It is obvious that the fewer the number of the above mentioned details, the simpler will be the test, errors will be reduced to a minimum, and the wider will be its application to clinical work.

In our laboratory the Benedict-Myers method is still used for routine clinical work. Many visitors to our department, the majority of whom are making blood sugar estimations but are not trained chemists, have commented unfavourably on the fact that this method is still in use. The writer finds it difficult to agree with the opinions held. It is this fact, chiefly, which has prompted the publication of this paper.

In the course of the routine work of this hospital, approximately 40 000 analyses have now been made with this picric acid method. As a result of this experience, we are quite in agreement with Benedict in his assertion that rarely has the clinician been misled in the interpretation of blood sugar results obtained by the picric acid method. We have also frequently noted the fact, mentioned by Benedict, that the rate of return of the blood sugar to the normal level, as found with the picric acid method, parallels the clinical progress of diabetes more closely than the results of the Folin-Wu method, with which the decline in blood-sugar concentration is found to be more rapid. The reason for this may be found when blood-sugar methods become more exact. One possible explanation is suggested. Picric acid detects

* From the Department of Metabolism, The Montreal General Hospital.

sugars other than glucose, and the metabolism of some of these may also be disturbed

Some of the conditions in diabetes which lead to hyperglycæmia are dietary indiscretions, fever, suppuration, anæsthesia, and injuries (operations, etc.) These conditions have been observed frequently in our diabetic clinic, and a large amount of blood-sugar data concerning them have, in the course of time, accumulated. For example, as a routine, all diabetics have blood-sugar examinations before and one hour after operation, whether the anæsthesia used is general or local. In diabetics coming regularly to our clinic, the effects of fever, dietary indiscretions, etc., on the blood sugar are observed as a routine. In order to test the sensitivity of some of the more common blood-sugar methods in detecting alterations of carbohydrate metabolism, comparative studies were made of the Folin-Wu, Folin and Benedict-Myers methods. The accompanying tables show a summary of our experiences with these three methods for estimating blood sugar in two of the above mentioned conditions, namely, anæsthesia and dietary indiscretions.

TABLE I

THE EFFECT OF ETHER ANÆSTHESIA ON THE BLOOD SUGAR IN 31 CASES OF DIABETES MELLITUS MEASURED BY THE FOLIN WU, FOLIN AND BENEDICT-MYERS (PICRIC ACID) METHODS			
	METHOD		
	Folin Wu	Folin	Picric acid
Hyperglycæmia	23	18	27
No hyperglycæmia	8	13	4
Blood sugar per cent			
Maximum	232	196	256
Minimum	099	088	103
Average	188	158	227

It will be seen in Table I that of thirty-one cases, disturbances of carbohydrate metabolism following anæsthesia were found in twenty-seven with the picric acid method, in twenty-three with the Folin-Wu method, and in eighteen only with the Folin method. The picric acid method was therefore the most sensitive test.

The interpretation of the differences between the results of the two copper tests may be found in a study of the maximum, minimum and average blood sugar values, and in a detailed analysis of the data of individual cases. It might be expected that, while the Folin method is supposed to measure glucose only, the incidence of hyperglycæmia would be the same as with the Folin-Wu method, though the values would

differ, being higher with the Folin-Wu method, since this tends to measure the total reducing substances. That blood-sugar increase does occur is obvious from the following case. The blood sugars after anæsthesia were higher, as determined by the Folin method, than before it, but the increase was not sufficient to lead to a value corresponding to the accepted standard of hyperglycæmia. Thus

TIME	METHOD		
	Picric acid	Folin Wu	Folin
Before anæsthesia	0.111	0.097	0.074
After anæsthesia	0.166	0.133	0.098

From this it will be seen that the Folin-Wu method led to a result higher than the accepted limits of normality. Of all the tests the picric acid method showed the most marked degree of hyperglycæmia. This may be seen from a study of the maximum, minimum and average values recorded.

With dietary indiscretions the results are still more striking. During their periodical visits to the clinic all patients, as a routine, are asked about any changes in diets that may have been made. All of the patients recorded here admitted alterations in diets, some voluntarily, emphasizing that there was no sugar in the urine in spite of the changes, in order to obtain increases of diet. The subjects used in this investigation included only those whose blood sugars at previous visits were normal.

TABLE II

THE EFFECT OF DIETARY INDISCRETIONS ON THE BLOOD SUGAR IN 46 CASES OF DIABETES MELLITUS MEASURED BY THE FOLIN WU, FOLIN AND BENEDICT-MYERS (PICRIC ACID) METHODS			
	METHOD		
	Folin Wu	Folin	Picric acid
Hyperglycæmia	18	11	26
No hyperglycæmia	28	35	20
Blood sugar per cent			
Maximum	244	208	270
Minimum	106	079	125
Average	181	161	217

It will be observed in Table II that in spite of definite histories of dietary indiscretions, the Folin method, more specific for glucose than the other two, failed to record hyperglycæmia in thirty-five of the forty-six cases. It may here be observed that it does not follow that there were disturbances of the carbohydrate metabolism in all of these cases, but the fact remains that dietary indiscretion is the commonest cause

of hyperglycemia in diabetes, and that in many cases of such indiscretions, when the picric acid and Folin-Wu test indicated this condition, the new Folin method did not do so. A study of the maximum, minimum and average values again shows that the picric acid method was the most sensitive in detecting alterations of diets.

Apropos of the details of tests, such as the preparation of reagents and their stability, the writer does not know of any method which is more satisfactory than the Benedict Miers. Its greater simplicity makes for greater accuracy. The apparatus required is simple. Since errors due to surface oxidation are not as important as with the copper tests ordinary test tubes may be used. These are readily graduated with the aid of the pipette, at the 10 or 20 cc mark. The reagents are few and very easily prepared. The standard consists of glucose in saturated picric acid, which keeps almost indefinitely at room temperature. The only other solution is 10 per cent sodium carbonate. Since glucose is obtainable in pure form, the only impurity is to be found in the picric acid and the test for the

purity of this substance is extremely simple (Folin and Dorsey method).

RESUME

The selection of a method for blood sugar estimation, as for all laboratory methods, should depend upon a knowledge of the principles involved in the test and the use it is intended to make of the data. In clinical work, a blood sugar test fulfils its function only when it detects alterations of carbohydrate metabolism. Other considerations are simplicity of technical details of the test and the preparation and stability of the necessary reagents. The fewer the reagents required and the longer they keep under ordinary conditions, the more practical does the test become, the fewer the manipulations the simpler is the test and the less are the sources of error. Experimental data are presented which show that the picric acid method fulfils these conditions, and for routine clinical work its use is not only justified but ideal.

A COMPARISON OF THE BUFFER CAPACITY OF VARIOUS MILK MIXTURES USED IN INFANT FEEDING*

By ANGELIA M. COURTNEY, B.A., AND ALAN BROWN, M.B. (TOR.),

Toronto

BY the buffer capacity of a milk mixture is meant its effectiveness in holding added acid so that the degree of acidity of the mixture is not increased in proportion to the quantity of acid added. The buffer capacity of a milk mixture depends mainly upon the protein content with its acid-binding amino-radicals and those salts of its mineral content which react with added acid to form acid salts. Thus, one of the buffer salts of milk is basic potassium phosphate, which uses a definite quantity of the added acid and thereby forms acid potassium phosphate, in contrast to this neutral sodium chloride makes no demand upon added acid.

According to Marriott,¹ one of the outstanding advocates of acid milks in infant feeding, the hydrogen-ion concentration of the stomach con-

tents of normal breast fed infants at the height of digestion is pH 3.75 while that of normal infants taking cow's milk varies from pH 4.75 to pH 5.3. He calls attention to the fact that it requires from three to four times as much hydrochloric acid to bring the hydrogen-ion concentration of sweet cow's milk to pH 3.75 as it does to bring breast-milk to the same pH . Lactic acid milk, on the other hand, needs little more than breast-milk does. That is, sweet cow's milk has three to four times the buffer capacity of breast-milk, but in lactic acid milk the buffer is materially reduced and the hydrogen-ion concentration increased by the lactic acid produced in the souring.

Schliff and Mosse,² in a monograph on the use of acid milk mixtures in infant feeding, emphasize the importance of maintaining a normal stomach acidity, particularly to prevent abnormal bacterial break-down of food, also to

* From the laboratories of the Sub Department of Pædiatrics of the University of Toronto and the Hospital for Sick Children, Toronto.

favour peptic digestion There are many other writers who advocate the use of food mixtures designed to prevent the lowering of stomach acidity whose work will not be reviewed here

A comparison of the buffer content of various food mixtures and forms of milk used in making them has been carried out in this laboratory The object was to obtain information as to their relative value as agents in the prevention of the lowering of stomach acidity

The method used was an application of that of Levy, Rowntree and Marriott³ for the determination of the hydrogen-ion concentration of blood of which an adaptation was made by Kiamei and Greene⁴ for the estimation of the hydrogen-ion concentration of milk and by Tisdall⁵ for that of stools The treated samples were dialyzed in collodion sacs against freshly boiled distilled water for thirty minutes, and the hydrogen-ion concentration of the dialyzate was estimated colorimetrically For the colorimetric reading, samples to which the appropriate in-

dicator had been added were compared with Clark's colour chart, and the readings were checked by comparison with tubes containing Sorensen standards The Clark chart is accurate and easily used in the range required for this investigation and served as a permanent standard in case the Sorensen standards were found to be spoiled when needed To use this method successfully extreme care is necessary, both in the rinsing of all containers with freshly boiled distilled water, and in the use of uniform tubes and uniform amounts of sample and indicator for the colorimetric comparison

The results obtained are given in two tables In Table I the foods are arranged in the order of their nearness to breast-milk as regards the effect on hydrogen-ion concentration of adding to each the same amount of N/10 HCl, 2 cc This quantity was selected as that which, under our conditions, was found to raise the hydrogen-ion concentration of ten cc of breast milk approximately to the optimum stomach acidity

TABLE I
EFFECT ON PH OF ADDITION OF 2 CC N/10 HCl TO
10 CC OF FOOD AVERAGE VALUES

Food	Initial pH	Resulting pH
Breast milk (various mothers)	7.0	3.6
Butter soup, 2/3, water, 1/3	6.7	2.7
Butter soup, 2/3, lactic acid milk, 1/3	4.2	3.5
Butter soup, 2/3, protein milk (powder), 1/3	4.8	3.5
Butter soup, 2/3, lactic acid milk (powder), 1/3	4.9	3.7
Lactic acid milk	4.3	3.9
Protein milk (powder)	4.6	3.9
Acidulated S.M.A. protein, proprietary protein milk	4.4	3.9
Lactic acid milk (powder)	4.7	4.2
Thick feeding made with 25 oz 2% lactic acid milk and 2½ oz farina	4.6	4.2
Butter soup, 2/3, evaporated milk, 1/3	6.4	4.7
Butter soup, 2/3, pasteurized milk, 1/3	6.7	4.8
Pasteurized milk dilution, 7 oz in 20, with 1 oz cane sugar	6.8	4.9
S.M.A. (proprietary reconstructed breast milk)	6.7	5.2
Evaporated milk, dilution, 12 oz in 40, with 1 oz Imperial granum, cooked 6 hours	6.3	5.3
Evaporated milk, dilution, 10 oz in 30, with 1 oz barley flour	6.4	5.3
Recolac (proprietary reconstructed breast milk)	7.5	5.5
Evaporated milk	6.5	5.5
Similac (proprietary reconstructed breast milk)	7.3	5.8
Pasteurized milk	6.7	5.8
Thick feeding made with 20 oz 2% pasteurized milk and 2 oz farina	6.5	5.9
Dryco (proprietary dried milk)	6.7	5.9

TABLE II
ACID REQUIREMENT TO BRING PH OF FOODS APPROXIMATELY TO pH 3.6 AVERAGE VALUES

Food	Initial pH	CC Added Acid	Resulting pH
Breast milk	7.0	2	3.6
Butter soup, 2/3, water, 1/3	6.7	0.6	3.5
Butter soup, 2/3, lactic acid milk, 1/3	4.2	2	3.5
Butter soup, 2/3, protein milk powder, 1/3	4.8	2	3.5
Butter soup, 2/3, L.A.M. powder, 1/3	4.9	2	3.7
Lactic acid milk	4.3	2.6	3.6
Protein milk powder	4.6	2.6	3.8
Lactic acid milk powder	4.7	2.7	3.7
Butter soup, 2/3, evaporated milk, 1/3	6.4	3.0	3.5
Butter soup, 2/3 pasteurized milk, 1/3	6.7	3.0	3.7
Pasteurized milk dilution, 7 in 20	6.8	3.0	3.5
S.M.A., proprietary breast milk	6.7	3.5	3.6
Thick feeding made with L.A.M.	4.6	4.5	3.7
Evaporated milk dilution, 12 in 40, long cooking	6.3	4.5	3.5
Recolac (proprietary breast milk)	7.5	5.0	3.6
Similac, (proprietary breast milk)	7.3	5.0	3.7
Evaporated milk dilution, 10 in 30	6.4	5.25	3.6
Evaporated milk	6.5	7.0	3.6
Pasteurized milk	6.7	5.0	3.5
Thick feeding made with undiluted pasteurized milk	6.5	8.5	3.5
Dryco	6.7	9.5	3.7

during digestion, according to Marriott, pH 3.75

In Table II are given the results of an attempt to determine how much N/10 HCl is required to bring each of the foods approximately to the above-mentioned hydrogen-ion concentration and the order of arrangement is that of nearness to breast milk in the number of cubic centimetres needed to accomplish this. Many trials were necessary with some of the mixtures before the desired pH was obtained, and accordingly the averages in Table II for the most part represent a smaller number of determinations than do those in Table I. However, the foods fall into nearly the same order of arrangement in both tables.

SUMMARY OF FINDINGS

Butter soup, two thirds, with lactic acid or protein milk, one-third, gives a food which makes about the same demand upon stomach acidity as breast-milk does. The undiluted acid milks rank in this respect slightly lower than the butter-soup mixtures, and in their class falls acidulitised S. M. A. Protein, a proprietary protein milk. Lactic acid milk-powder seems to contain a little more buffer than the liquid milk or protein milk-powder.

The next class in the order of amount of buffer content includes the butter soup, two-thirds, evaporated or pasteurized milk, one third mixtures, and a seven parts in twenty ordinary milk dilution. These require 50 per cent more acid than breast-milk does to bring them to pH 3.75.

The next group includes two evaporated milk dilutions with added carbohydrate, one, ten parts of milk in thirty, and the other twelve parts in forty, and cooked six hours. With these are to be classed three reconstructed breast milks, S. M. A., Reolae and Similae, also a thick feeding made with lactic acid milk. Except S. M. A., which really lies between this group and the preceding, the foods of this class need about two to two and one-half times as much acid as breast-milk to bring them to pH 3.75.

The remaining foods in the tables are undiluted milks, unless the thick feeding made with undiluted milk is actually concentrated. These require upwards of three times as much acid as breast milk to bring them to approximately pH 3.6. The differences among the whole milks shown in Table II must be of

some significance, for the separate values making each average varied but little. The reconstruction of the dried and evaporated milks was carried out in the dairy as if for ward use and not with laboratory exactness, but the findings ran almost the same from day to day.

It was interesting to find with Diyeo that, though not very much more acid was needed to bring it to the desired acidity than in the case of pasteurized milk, it showed small response to successive increases in the amount of acid added after a certain point. This behaviour is shown in detail as follows: 8 cc N/10 HCl to 10 cc of the milk, pH 4.3-4.1, 8.5 cc acid, pH 4.2-3.9, 9 cc acid, pH 4.0-3.8, 9.5 cc acid, pH 3.8-3.6, 10 cc acid, pH 3.5, 10.5 cc, pH 3.5-3.4. The finding with 9.5 cc acid seems to be most nearly comparable with the values in Table II as a whole.

One of the food mixtures in the list forms a class by itself. This is butter soup, two thirds, water one third, in which the buffer capacity is less than in breast milk. This food needs only 0.3 as much acid as breast milk to bring its hydrogen ion concentration to pH 3.75.

The information derived from these observations seems to suggest another reason for the favourable effect of the use of the acid milks in combination with other food mixtures. It has been our observation in the feeding of many hundreds of infants that when an acid milk is combined with, say, a butter-flour mixture, or even formula, the clinical results are distinctly more favourable than when these are used in combination with ordinary sweet milk. The procedure of combining butter soup with either cultured lactic acid milk or lactic acid milk-powder or protein milk-powder is merely another link in the physician's armamentarium in feeding certain difficult cases. That all thick cereal mixtures be made with acid milks is also suggested, as an improvement over the use of sweet milk in their preparation.

Thanks are due Miss Jean Hutt and Miss Bertha Coates of the dairy for their great assistance in preparing the material for this work.

A METHOD OF SERUM THERAPY FOR SEPTICÆMIA*

BY FRED T. CADHAM, M.D.,

Winnipeg

IN any discussion on septicæmia it appears necessary to define the term. Admittedly that is difficult. Infection may exist as a small localized focus, or as a condition where all defenses of the body are overcome and the micro-organisms travel freely through and even, on occasion, proliferate in the blood stream. Between these two extremes lies a wide variety of clinical conditions. The terms septicæmia, bacteraemia, sepsis, pyæmia, and sapræmia are supposed to define certain of these conditions, and to convey to the mind a definite clinical picture. So often, however, do the conditions indicated by these terms grade into one another that a sharp line of distinction cannot be drawn. The very nature of pyæmia, a condition of supposed localized and circumscribed areas of infection, suggests a previous invasion of the blood stream, nor is a subsequent invasion impossible.

Commonly, the term septicæmia is applied to states associated with the finding of bacteria in the blood stream. Increased knowledge, however, derived from the perfection and extension of blood-culture methods, has shown that in many diseases, not designated or recognized as septicæmia, bacteria are to be so found. Invasion of the blood stream, for longer or shorter periods, by the causative organisms is now frequently noted in such diseases as typhoid and pneumonia. Moreover, it is to be expected that in the course of syphilis there has occurred at some time between the onset of the primary lesion and the appearance of the secondary manifestations an invasion of the circulatory system. Again, we distinguish between a meningitis and a meningococcal septicæmia, though the organism may be recovered from the blood in both conditions. As Churchman¹ states "A definition of septicæmia free from all possible objections would appear to be impossible to frame."

There exists, however, a class of cases in which the symptoms due to a general invasion

overshadow those of local origin and which is characterized in part, clinically, by an irregular fever—the so-called septic temperature—by chills and sweats, and associated with a more or less constant invasion of the blood stream by micro-organisms. To such we may apply the term septicæmia. On occasion it is designated by its source, as puerperal or endocardial, also, the name of the causative organisms may, with advantage, further define the condition. Thus the term "puerperal streptococcus septicæmia" designates a fairly clear clinical condition.

The treatment of these patients, and almost without exception their condition is serious, has always been difficult and nearly always discouraging. We lean on general measures in the attempt to increase the patient's resistance, and we try special methods in the hope of destroying or attenuating the infective micro-organism. When feasible, surgical intervention for the elimination of foci is the rule.

The general methods of treatment have been skilfully set forth by Sir Thomas Horder.² They include careful nursing, rest, and selected diet. It might not be out of place here to note two of the points he stresses in the care of these patients, namely, the prompt recognition of the condition, and the prompt institution of a definite method of treatment.

It appears likely, however, from our present knowledge, that it is in the further development of one or all of the special measures, that is, the use of serums, vaccines, foreign proteins, and the intravenous use of the dyes, that success may be ultimately looked for in the treatment of septicæmia.

A simple and obvious principle may be stated at the outset, that, since in this condition there is a definite failure of the body tissues to organize the required resistance or immunity, it would appear logical, if possible to supply that immunity in passive form. All are familiar with attempts that have been made in this direction. For instance, take the

* From the Department of Bacteriology, University of Manitoba Medical School.

case of antistreptococcus serum Since the micro-organism most frequently associated with septicæmia is a streptococcus, various stock antistreptococcal serums have been prepared and placed on the market Too often they have proved a frail reed

It will be of advantage to the argument to consider some of the possible reasons why the use of such serums has not resulted in more success First many types of streptococci that may be responsible for a septicæmia exist, and a stock serum too often lacks the essential antibodies for the type causing the infection in the patient under treatment With cultures of streptococci obtained from twelve patients with a streptococcus septicæmia, I failed to obtain agglutination of the causative organisms by various stock serums in ten, and a partial agglutination was noted in but two instances However, it is fair to state that the agglutination power of a serum is not an exact criterion of its efficacy, nor does the apparent absence of that power necessarily indicate that such a serum is without therapeutic value

Second several humoral factors are concerned in the reaction that eventually leads to the destruction of an infective micro-organism following the administration of a specific antiserum Ehrlich established the belief that in the body tissues there occurs a reaction between the antibody contained in the plasma and the foreign body (infective agent) This may take the form of the action of an antitoxin on its toxin, or of the agglutination of the foreign body, or the precipitation of its products through the action of a specific antibody, or of a union of the foreign body with its particulate antibody The latter may cause a destruction of the foreign body which, in the case of bacteria, is demonstrated by the death or lysis of the bacterial cell Now to facilitate the lysis or death of a bacterium *in vitro* by its specific antibody, complement (alexin) a substance or state normally present in the blood serum is required It is reasonable to infer, even if there exists but limited experimental evidence to support the inference, that *in vivo* complement fulfils a similar and important function

Now the complement power of the person suffering from infection may vary widely³ Sufficient complement to complete the reaction

between the micro-organism and its specific antibody may be looked upon as an asset if not a necessity It is suggested that if the blood of the patient is low in complement power, then the inoculation of a serum containing definite antibodies to the infective bacterium may fail to give the expected beneficial results Such was found to be the case in six patients investigated, who showed a low complement power in the blood, and who failed to improve with the administration of a serum containing immune bodies corresponding to the micro-organism causing the infection Conversely, an investigation of six patients who were not doing well, and whose blood gave a high complement power, showed that the antibody content of their blood serum for the infective organism was low

Besides the use of stock antistreptococcus serums some further attempts at therapy along this line have been made Sir Almroth Wright⁴ introduced a method to which he gave the name "immuno-transfusion" The blood is withdrawn from a donor inoculated with a fixed amount of a vaccine, and a few minutes to an hour subsequently the patient is transfused with this blood Later, Colebrook and Storer⁵ suggested the use of defibrinated blood from a donor who had been inoculated with a vaccine one to five hours previous to the time of the withdrawal of the blood They reported some success A further method of transfusion of immunized blood has been described by Hooker,⁶ Diek,⁷ and several others A donor was immunized with a vaccine and, after several days, the patient was inoculated with this donor's blood Good results have been reported in several cases treated by this latter method

The value of transfusions of normal blood in septicæmia has long been a matter of dispute Here, if a definite specific action on the invading organism is expected, one pre-supposes that the donor has the required immune bodies in his serum The method advocated by Polak of small repeated transfusions seems to have given the most favourable results One must bear in mind, however, that in whole-blood transfusions, even on occasions when the bloods appear compatible *in vitro*, the donor's blood cells may be destroyed in the circulatory system of the patient This throws a further

burden on the immunity mechanism of the patient, and an added burden on the complement reserves of the body. Moreover, transfused whole blood, as suggested by Wright, may form a pabulum for the further multiplication of the infective organisms.

In view of the above considerations it appeared logical to attempt to treat some of these patients by the inoculation of an animal serum containing immune bodies, and during the same period with transfusions of human serum. Within the past three years eighteen patients diagnosed as clinical cases of septicæmia, and who had shown repeated positive blood-cultures, were treated. Of these sixteen recovered.

The method adopted was as follows. The invading micro-organism was obtained from blood cultures and grown in serum-glucose broth. The resulting growth having been centrifuged three times in normal saline, a vaccine, in which the micro-organisms had been heat-killed at the minimum lethal temperature, was then prepared, and inoculated into rabbits and guinea pigs. These animals tolerate comparatively large doses of a vaccine containing either streptococci or staphylococci, especially if the organisms are washed free of the media. The dose of the vaccine, starting with one-quarter billion and working up to three billion organisms, was given on alternate days. An agglutination titre of one to five thousand may be obtained as early as the sixth day. Any time after the fifth day blood was withdrawn from the heart with aseptic precautions, and without causing the death of the animal. This blood was placed in the ice chest for eight hours, and then the serum was pipetted off. The patient was inoculated subcutaneously with from three to four c.c. of this serum. Twelve patients were treated with rabbit serum, and six with guinea pig serum. There seems to have been no appreciable difference in the result obtained.

A donor whose blood was completely compatible with that of the patient was obtained as soon as possible. The donor reported at the laboratory and from 50 to 60 c.c. of blood were withdrawn in large vacuum tubes. This was left at room temperature for fifteen minutes and then placed in the ice chest for fifteen hours. The serum was next pipetted

off with all aseptic precautions, examined for sterility, diluted with equal parts of saline, and given by means of a syringe to the patient intravenously. Thus, the patient received an inoculation of the animal serum containing the antibodies subcutaneously, and also received a transfusion of from 25 to 30 c.c. of the donor's serum containing complement. Originally, the treatments were given one week apart, but this was subsequently shortened to two-day intervals. Treatment was continued until negative blood cultures were obtained and the patient showed considerable improvement. The greatest number of treatments given to any one patient was seven.

To isolate the infective organism, culture it, inoculate the animal with the vaccine, and to await the development of amboceptors of value, required at least five days, and to obtain a serum with a more powerful agglutination titre, twelve days. Frequently, the emergency of the case did not brook any such delay. To overcome this difficulty some rabbits and guinea pigs were inoculated with various strains of streptococci and staphylococci. Certain animals received inoculations of a vaccine prepared from fifteen strains of streptococci, which had been obtained from as many different cases of local or general sepsis. Patients were treated at once with the serum from these animals, pending the development in other animals of a specific serum.

ILLUSTRATIVE CASE

Mrs. S., aged 39, strong and healthy, suffered a miscarriage on December 28. On December 31 she complained of feeling chilly, and her temperature rose to 103° F. The temperature continued to range from 97° to 105°, associated with chills and sweats. On January 13th the blood culture showed a hæmolytic streptococcus. On January 20th she developed a panophthalmitis of the right eye. In addition there was a cellulitis of both heels. Petechial hæmorrhages had appeared on the limbs. The patient was weak, listless, and rapidly losing ground. The complement power of the blood at this time showed 60 per cent of the normal. On January 21st, 30 c.c. of human serum were administered intravenously, and, on January 23rd, 3 c.c. of serum from a rabbit which had been immunized with the streptococcus were given subcutaneously, also 30 c.c. of human serum, intravenously. Next day the patient stated that she felt much better. The chills and sweats ceased. The temperature remained lower and changed in type (see Chart I.). The pulse also improved in quality. On January 30th the combined serum treatment was again administered. Blood culture on January 31st was negative. Her condition rapidly improved, the temperature dropped, the panophthalmitis and cellulitis subsided. The complement power of the blood returned to 90 per cent of normal. She went on to complete recovery, though the sight of the eye was lost.

CHART I—A, combined treatment given

COMMENT ON CASES

All the patients, except one (No 13, Table I) were seen only when the course of the disease was well advanced. Each case was considered grave, and this method of treatment was instituted with the majority as a last resort. A definite beneficial response within twenty-four hours of the administration of the first injections of serum was noted in five of the patients, while in the others the improvement was gradual. In two instances the fever fell by crisis (see Chart II), in several there was a distinct change in the type of the curve (see Chart I), and in all cases the swing of the extremes in temperature was modified following the treatment. The pulse improved in quality with the smoothing out of the temperature

About or coincident with the time of obtaining a negative blood-culture a quick and distinct improvement in the patient's general

CHART II—A, combined treatment given

TABLE I
SUMMARY OF CASES

Case	Age Years	Origin	Blood Culture	Complications	Day of Disease Treatment Instituted	Complement power of patient's blood per cent of normal	Number of combined treatments	Day following first treat- ment that negative blood culture was noted
1	39	Puerperal	<i>S. hemolyticus</i>	Panophthalmitis

				Endocarditis	25	60	3	7
				Cellulitis of arm	8	90	3	7

Recovery in cases except Nos 6 and 16

condition took place. This was a characteristic feature.

Two patients had developed a panophthalmitis, this condition subsided without surgical interference, following the use of the serum, but the sight of the eye in each case was lost.

While undergoing treatment one patient (No. 3) developed an abscess of the lung. Her general condition, however, continued to improve, and the blood-culture was reported negative. Aspiration failed to relieve the abscess, but she expectorated quantities of pus containing abundant hæmolytic streptococci, and the condition eventually cleared up.

Another patient (No. 14), when first seen, had multiple cutaneous abscesses. Later, and subsequent to treatment, the inflammatory area about these abscesses subsided, and, while staphylococci could be noted in the stained smear of the aspirated material, yet the organisms failed to grow in culture.

One patient (No. 6) was suffering from an extensive cellulitis of the arm, following an injury. Blood-cultures showed the presence of both streptococci and staphylococci. A paralytic state of the bowel had developed, with extreme distension of the abdomen, and she was able to take only a small amount of liquid nourishment. She was semi-conscious. Following the serum treatment the temperature became lower. However, the abdominal distension progressed, and she died in four days. The blood-cultures in this case remained positive.

Another patient (No. 16) with otitis media, whose blood-culture showed the presence of hæmolytic streptococci, developed a mastoiditis followed by symptoms of meningitis. This patient had been treated with mercurochrome and polyvalent antistreptococcic serum without benefit. When seen, he was unconscious. He was given one of the combined treatments, but his general condition remained unchanged, and he died two days later.

DISCUSSION

Naturally, the question arises, how can transfusions of such a small amount of serum as 25 to 30 cc. diluted as it must be in the recipient's blood, be of value? However, experimental evidence has shown that, both *in vitro* and *in vivo*, blood with a weak or inactive

complement-power may frequently have that power raised (the complement reactivated) by the addition of small amounts of fresh serum high in complement-power. In the early stages of an acute infection, and as noted in two cases of this series, the complement-power of a patient's blood may be above normal. Since this power may fall with comparative rapidity during the progress of the disease, it was thought advisable to give the transfusions in all cases.

An investigation, after treatment, of the blood for opsonins in six of the patients not only demonstrated an increase of the bactericidal power of the serum, but also showed that the patient's opsonic index to the infective micro-organism was raised. The inference has been drawn that the transfusion of fresh serum reactivates the complement or stimulates its formation with a beneficial result to the patient, but, that such a result depends entirely on bacteriolysis through the action of complement lacks proof. Bacteriotropins (immune opsonins), similar to those found in the homologous immune animal serum, may also be transferred with the human serum, giving rise to an increase in phagocytosis. Moreover, the possibility arises that occasionally a bacteriophage for the infective micro-organism may exist in such serums and be transferred to the patient.

The animal serum containing antibodies was inoculated subcutaneously, contrary to the accepted procedure of giving such serums intravenously. On two occasions in which I gave this serum intravenously the patients experienced within a half an hour a severe reaction, characterized by faintness, pallor, sweating, and feeble pulse. Whether the reaction was due to anaphylaxis, or to a sudden liberation of bacterial toxins from the destruction of the bacteria, or to some other cause, I was unable to determine. Subsequent tests showed the cutaneous reaction to be negative to the serum. I found that the animal serum was absorbed rapidly, when given subcutaneously.

A local reaction, characterized by hyperæmia and swelling at the site of inoculation, developed after the third or later treatment with the animal serum in four of the patients. However, this anaphylactic reaction subsided within three days after discontinuance of the treatment. It

was expected that a reaction might be noted following repeated transfusions of human serum. Only one patient, however, showed a slight reaction—faintness, followed by a sweat coming on within fifteen minutes of receiving the fifth transfusion.

Evaluation of the results of a method for the treatment of septicæmia is a difficult matter. We turn to experiment, but experimental study lacks finality because of the resistance of laboratory animals to bacterial blood-invasion. Then, too, individual cases show a wide variation from each other, not alone because of the variation in the resistance of the host, but also because many different micro-organisms or different strains of the same organism may be responsible for a septicæmia. Moreover, on occasion, patients with septicæmia, even those severely ill, will recover without therapeutic aid.

The results obtained in the patients treated appear to justify a further trial of this method.

SUMMARY

Eighteen patients with septicæmia were treated with repeated inoculations of a homologous immune animal serum, and during the same period with repeated transfusions of human serum. Sixteen of the eighteen recovered.

INFECTIONS OF THE EAR, NOSE AND THROAT FROM THE GENERAL PRACTITIONER'S VIEWPOINT*

By L. DE V. CHIPMAN, M.A., M.D., C.M.,

Saint John, N.B.

IT was the writer's good fortune to be in general practice for five years, and it is with the general practitioner's problems in mind that this subject is treated.

INFECTIONS OF THE EAR

Infected ears naturally fall into two classes, viz, acute and chronic. This is not a mere arbitrary division, but is of the utmost importance. As we shall see later, one can take chances on symptoms in an acute aural infection that would be fatal in a chronic one.

Let us picture an acute case, an ordinary acute otitis media, such as you frequently see. There is usually a history of a "cold", or evidence of adenoids, there is pain in the ear, in infancy often indicated only by restlessness and crying, there is fever and impaired hearing. Examination of the ear reveals a reddened, bulging drum, with all landmarks obliterated. This is the typical picture though there are frequent variations from the above symptoms. There may be no pain and no fever,

we may see the case early when there is no bulging, in which event one can be content to wait and watch developments.

When the drum is bulging the treatment is obvious. As in surgery elsewhere cut down upon the pus. The drum should be freely incised. The technique of this little operation is important. The knife should be held delicately between the thumb and first two fingers, so that nothing can drive the knife with force, even if the patient jumps. The incision should be made in the lower part of the drum and continued in a curved direction up the posterior part. It is a difficult little operation if done with perfect technique, but with the modern electrically illuminated otoscope, even if one is not accustomed to working with one eye and a head mirror, one can make a simple puncture, and a simple puncture is better than nothing. The beginner is most apt to fail through incising the swollen posterior canal wall in mistaking it for the drum. One free incision is enough. Do not scarify the drum.

We have now reached the second stage

* Presented under the extra mural lecture course in New Brunswick.

Either the drum has been incised, or it has ruptured, and we have an acute discharging ear. The all-important thing now is to keep the ear clean. It is astounding how often one sees these ears almost hermetically sealed with a wad of pus-soaked absorbent tugged tightly into the canal. Often the parents are told to syringe the ear two or three times a day, and keep cotton in the ear between times, and this is the result. Such treatment is entirely unsurgical. These ears should be cleansed at least every two hours when the discharge is profuse, and as much oftener as necessary to keep them clean. Instruct the mother or nurse first, to put in a few drops of peroxide which will soften the pus, secondly, to syringe the ear thoroughly with a hot solution of boracic acid, thirdly, to instil a few drops of a saturated solution of boric acid in alcohol, then wipe dry.

Much has been written about the so-called dry method of treatment of these ears, i.e., wiping or sucking out the discharge instead of syringing. Doubtless the ideal method would be to cleanse them thoroughly with cotton and then use gentle suction several times a day, but if you can get a mother or even a trained nurse to do this efficiently you are exceptionally fortunate. The use of the syringe is practical and gives results.

Be careful to give detailed instructions about the method of syringing. The amule is to be drawn upwards and backwards, so as to straighten the canal. The tip of the syringe is to be put well within the canal and in the direction of its axis then use copious quantities of solution. A soft all-rubber ear-syringe is good but better still, use a fountain syringe with a quart of warm solution.

How long shall we continue this treatment, and when should we look for beginning mastoid complication? You may take it as a general rule that, if it is a first attack, you can safely watch an acute otitis for ten days.

Let us suppose we have two cases which have been discharging for the ten-day period under consideration. In the one case the discharge is as profuse as ever, or even more so. Look into the ear, and we see that, after wiping away the discharge, the canal fills rapidly, and when the drum is seen pus pulsates through a small opening. The canal wall is reddened

and swollen, so that the lumen of the canal is encroached upon. There is tenderness over the tip of the mastoid and perhaps over the body of the mastoid. There is a leucocytosis of 12,000 or more, and sometimes fever, but do not put too much stress on its absence.

The other case manifests the opposite of all these conditions. The discharge has gradually become less in quantity and improved in quality. When the ear is cleaned out, it remains clean for a considerable time. There is no pulsating discharge through the drum, the canal walls do not sag and bulge, mastoid tenderness has disappeared, and the white cell count is nearly normal. There is a feeling of well-being in the patient which is absent in the first case.

The first case will probably need a mastoid operation. The second, nine times out of ten, will get well without further trouble. If it does not, how long shall we wait? If all possible care has been given, the ear constantly kept clean, adenoids and tonsils removed, when necessary, and general health cared for, then, if the discharge persists freely, after five or six weeks treatment, it is much better to do a mastoid operation than to go on with a chronic running ear. If properly done, the operation is practically without danger and results are good in every way, whereas a chronically running ear impairs hearing, and is always a menace and a burden.

A word about the acute aural inflammations which arise as complications of the exanthemata or of pneumonia. Often the symptoms are masked and only constant alertness will afford an early diagnosis. The treatment is essentially the same, with the exception that the patient's general condition is of more importance when considering operation.

With a chronic discharging ear one is always, figuratively speaking, sitting on a powder barrel. Acute symptoms are to be considered with utmost seriousness. Pain or distressed feeling in the head, especially if associated with temporary suppression of the discharge, dizziness, the presence of polypi in the canal, a foul discharge with dead bone palpable by an attic probe are all danger signals, and are indications for a radical mastoid operation. In the absence of these

symptoms cleansing is usually all that is required. The point to be remembered and impressed upon our patients is that the development of these chronic affections can be prevented by treatment, with systematic follow-up and control, of all acute cases.

INFECTIONS OF THE NOSE AND THROAT

We cannot to day be content with making our general examination from the neck down, as we used to do, and simply hope that there is nothing above that disturbing our patient. It is being generally recognized throughout the medical world that a very large proportion of our office patients, the chronically unwell class, are primarily suffering from upper respiratory tract infection. The vast number of people complaining of headache, neuralgias, neurasthenias and migraines, of chronic cough, bronchitis and asthma, of arthritis and so called chronic rheumatism are being studied as never before, and, in a large proportion of these cases, the original focus is being traced to infection in the nose and throat. Is this merely a fad, or perhaps a tendency of the medical pendulum to swing to extremes? Let us consider the reasonableness of the proposition. In the nose are two mucosa-lined passages, each connected with a whole series of blind sinuses or cavities, often with inadequate ventilation and drainage. Through this passage, or through the mouth, must go all the air we breathe. Now, under our modern civilization, in a northern winter climate, we take thirty, forty, yes even sixty children, put them in one room for two or more hours at a time, raise the temperature to between seventy and eighty degrees, have the air so dry that it irritates not only the delicate mucous membranes but even the tough skin, add some chalk dust, and then allow half a dozen children with acute coryza to cough germs around promiscuously. Can we wonder that nasal infections are prevalent? Then given a chronic nasal infection, with germ-laden discharge pouring out day and night, some of it being swallowed, some aspirated into the bronchi, the natural sequence seems to be chronic systemic disease and depression.

Nose and throat infections then are important enough to bear in mind when examining any one in chronic ill-health. What are we to

look for, and how can we go about making a diagnosis in the few minutes at the disposal of a busy practitioner? As in other infections, we have to deal with acute and chronic phases.

Acute infections are comparatively simple to diagnose. There is usually a history of cold in the head, which persists, often with pain and tenderness around the eye or brow. A persistent cold in the head, with one sided nasal discharge, is a definite sign of sinus infection.

If the membranes are much swollen, shrink them by packing the nose lightly with 5 per cent cocaine for five minutes using thin cotton pads dampened with the solution. This gives better ventilation and drainage. If you have any sort of suction apparatus apply it several times for short intervals. Next, pack the nostrils with cotton pledgets soaked in 10 per cent argyrol. Tease out a thin layer of cotton on the first joint of your left thumb. Soak thoroughly with argyrol then, holding one end over an applicator slide it along the septum to the upper posterior part of the nostril on each side and leave it there for twenty or thirty minutes. Repeat this treatment daily. These pledgets seem to have an osmotic effect. Copious secretion results so that the patient must be provided with a large gauze handkerchief. There is often spasmodic sneezing and reddening of the eyes, but the patient is greatly relieved and the head feels clearer. This simple treatment will clear up many an acute sinusitis and be helpful to all acute rhinitis cases. It should of course be combined with general treatment, such as careful diet, rest, and proper ventilation.

Coming to chronic nasal infections, we have a difficult field which needs all the skill we can possibly acquire, for many cases are overlooked even by men whose special field this is. There are, however, certain basic principles of examination, easily mastered, which will indicate the trouble, if present, in the great majority of cases.

First, as in all diagnosis, the history is of great importance. These patients usually do not complain primarily of nasal symptoms, but rather of those suggesting tuberculosis. There is languor, fatigue, often cough with morning sputum, and bronchitis, sometimes a slight evening rise in temperature. Hoarse-

ness is frequent, and nervous symptoms, such as headache, depression, neuralgia, migraine and neurasthenia are usually present in some degree. In a recent analysis of 100 cases I found that 32 per cent, practically one-third, complained of head-pains of some description. Frontal and occipital pain is most common. There is usually phlegm in the throat and post-nasal dropping, with an occasional bad taste in the mouth, especially in the mornings, but the patient may be so accustomed to this that he is entirely unconscious of it and only questioning will bring out the complaint.

The patient comes then with obscure head-pains or neuralgia, post-nasal discharge and general depression. Sinus infection must be considered. How are we to find out more about it? Under good illumination with a head mirror examine the nostrils and note whether the passages are free or blocked. In a normal nose with fairly straight septum the inferior and middle turbinates hang freely in the nostril and are easily seen. There is ample room for ventilation and drainage. A blocked, obstructed nostril predisposes to sinus infection. Beware, however, of putting too much stress on a curvature in the septum or a spur. Frequently these are innocent of real harm and should be left alone, unless causing symptoms such as real obstruction to breathing, frequent colds with blocking of discharge and pain. The submucous operation for straightening the septum is an invaluable operation when needed, but it is much over-worked.

Next examine the mucous membranes. The normal mucous membrane has a clear, glistening, ruddy appearance, more easily recognized than described, and very different from the boggy, deadened appearance of the membranes so frequently seen in chronic sinus cases. Observe any discharge which is visible, and note if it comes from under or over the middle turbinate. Then, if there is much blocking of the nostrils or swelling of the membranes, pack the nostrils lightly with 5 per cent cocaine for ten minutes. This will, by shrinking, give us a much better view and allow discharge or polypi, formerly invisible, to appear. Suction applied at this stage is also valuable.

Next transilluminate the sinuses. This is a valuable adjunct to diagnosis. It is simple,

quick, easy, and often puts one on the right track. Compare the clearness of the two sides carefully, under different degrees of illumination. Do not forget to remove any upper artificial dentures. Should one antrum appear dark, antrum puncture is of great value in substantiating the diagnosis.

Last, but not least, comes x-ray examination. A good x-ray plate is a wonderful help, but unfortunately much experience and special technique are required on the part of the roentgenologist to make the plates reliable.

When once the diagnosis is established, the treatment is mainly surgical. If the condition is of recent standing, *i.e.*, within a year, usually fine intra-nasal drainage is sufficient, whether it be an antial, frontal, ethmoid, or sphenoid infection. In longer standing antral cases, the radical Caldwell-Luc operation is preferable. Only in persistent and severe cases is the radical frontal needed. With properly carried out surgical measures, the results in nearly all these cases are good, and often wonderfully good.

Before leaving the nose, a few words with reference to sinus infection in children are necessary. Sinusitis is much more prevalent in children than is generally realized. It is comparatively easily recognized if looked for. As with adults, the complaints frequently refer to general conditions. There is listlessness, loss of colour and appetite, and undernourishment. On examining the nose the mucous membranes are apt to be found swollen and boggy, and a muco-purulent discharge may be present. A nasal discharge in a child which persists, even after the removal of adenoids and tonsils, is fairly definite evidence of sinus infection.

Little time is left for the consideration of throat infections, but the tonsils must be referred to. Here, also, especially in adults, the history is of as much importance as the examination. Is your patient well? If not, why not? If he has pains in the joints, with poor general health, naturally, evidence of disease in the tonsil is of far more significance than if he were robust. One's tolerance for infection varies as much as his tolerance for whiskey, and it is the individual that we must treat, not the tonsil.

In examining the throat in adults, merely looking at the tonsils by pressing down the

tongue is of little value, though one may get a hint of disease if the anterior pillars are deeply injected. Large fibrous, ugly tonsils are often more innocent of disease than small buried ones. Take a retractor, pull back the anterior pillar and press on the tonsil. A thin milky or purulent discharge indicates the worst type. Large open crypts with white cheesy material often seem to do little harm. It is possible, use suction to bring out the character of the discharge. Often one has to rely on general symptoms, rather than local, together with a carefully taken history. I recall two

recent cases in which the tonsils were small with little apparent infection, but the patients each gave a history of periodic prostration and indigestion accompanied by an inflamed throat. We found a large buried abscess in one tonsil in each case. In children the size of the tonsils is important, also any enlargement of the anterior cervical glands.

It is impossible in a paper of this kind adequately to cover even one phase of the subject, but enough has been said to illustrate the practical importance of this work in every practice, and possibly to stimulate interest in it.

INTESTINAL GRIPPE (SO CALLED)

By FRANK H. BOONE, M.B.

Hamilton, Ont.

SINCE 1918 a term has arisen which is applied both by laity and physicians to certain types of cases. It has been used so generally that one must consider the possibility of the condition designated thereby, which is described throughout the world, and frequently called "intestinal gripe" or "intestinal influenza."

Influenza was epidemic in this country in 1918 and 1919, since then it has been endemic in the colder seasons. During this period of the year we meet the cases that have been classified as intestinal gripe. Most doctors, with whom I have talked, feel that some indefinite condition does occur during this time, which is closely related to influenza, but concerning the actual identity of which they are uncertain. I have discussed this subject with several whose practice is limited to children. All mentioned various patients they had seen with symptoms which they thought might be classified within this group. In some there was severe diarrhoea, with mucus, blood, and even pus. One must of course remember that bacillary dysentery occurs even in the winter months, personally, I recollect having seen proved cases in November, December and January. One paediatrician, whom I know to be a keen observer, went so far as to claim a seasonal incidence for intestinal gripe. During the months from November to January he had seen many patients in welfare clinics who gave the following history: sudden onset,

with violet vomiting, followed by marked anorexia, drowsiness, slight fever, and irritability. Usually there was some diarrhoea. He had observed this every winter for the last four years, and though he did not feel justified in saying that the symptoms were due to influenzal infection, he considered it possible. When reliable men express such ideas, one must hesitate before they are cast aside as purely imaginary.

Definite diagnosis, however, is complicated by the great number of widely different etiological factors able to provoke similar symptoms. It is well known that frozen milk will cause frequent and severe gastro-intestinal disturbances in young children. Parenteral infections of all types are so often attended by intestinal disturbances that in many cases of so-called intestinal gripe, I feel a differential diagnosis would be impossible. Recently the rôle of paranasal sinus and mastoid infection have been especially emphasized. John Thompson,¹ of Edinburgh, under the heading of parenteral infection, says, "The disturbance of the alimentary canal may be predisposed to by the acquisition of an infective condition in other parts of the body, such as catarrh (influenzal or other) in nasopharynx, ear, bronchi or urinary tract, which so weakens the patient as to set up a food disorder which would not otherwise have arisen."

For many years writers have mentioned gastric and intestinal symptoms in influenza,

both adults and children being affected, but mainly the latter. In many of the text-books, both old and new, the authors have included a gastro-intestinal type, but are not willing to recognize it as a distinct clinical entity. Frederick Lord,² writing in Osler's *Modern Medicine*, classifies influenza under nine headings. Of the gastro-intestinal type he says "This form of influenza is an entity of uncertain existence. The symptoms referred to this tract may be toxic phenomena, secondary to the respiratory and nervous form." He had never seen a case with absence of the respiratory symptoms in which the diagnosis was certain.

J. A. Light,³ during an epidemic of several hundred cases of influenza, was unable to find one case of a typical gastro-intestinal form. In many the abdominal symptoms were so marked, and those in other parts of the body so mild, that one might easily believe them to be the result of infection or some lesion of the gastro-intestinal tract. In none was he able to show this to be a fact. The respiratory symptoms were sooner or later recognized in all. He stated that in autopsies performed at the Mercy Hospital, Pittsburg, none revealed any characteristic lesion which could be attributed to influenza, unless one accepted hyperplasia of the solitary lymph-follicles as such. Dr. Oskar Klotz was quoted as finding no distinct gastro-intestinal lesions in autopsies on cases dying of influenza at the Magee Hospital. This writer also reviewed the article by Liehenstein on Influenza in the American edition of *Nothnagel's Encyclopedia of Practical Medicine*, which describes a pathological condition occasionally found in the gastro-intestinal tract, namely, a hæmorrhagic condition, and swelling of the Peyer's patches and solitary lymph-follicles, but he believed that these could readily be explained as being coincident or secondary, inasmuch as they might be found in the course of any acute infection. He felt it was obvious that the seat of primary infection in influenza was in the respiratory system, and that there were insufficient data to warrant the designation of a gastro-intestinal form. He believed that this form should be regarded rather as a complication or sequela.

In reviewing the current literature, I have found some variation in the types of abdominal and intestinal influenza or grippe described. I feel justified in roughly separating these reports

into two groups, one in which diarrhoea was seldom present, in the other, always present.

D. A. Rice and H. O. Williams⁴ reported ten cases, seen in five families during a mild epidemic of influenza, which they considered as possibly of an abdominal type. The symptoms noted were marked inflammation of the eyes, abdominal pain referred to the umbilicus, vomiting, and in some cases diarrhoea with considerable collapse. Pain in the muscles of the neck, legs and arms was also a marked feature.

F. Colmes⁵ reported three cases of spastic ileus associated with influenza. The onset was acute, with colic, persistent vomiting, and severe subjective symptoms. In all a diagnosis of intestinal obstruction was made, but unconfirmed at operation. He considered as possible causes the action of the central nervous system on the intestinal musculature, inflammation produced by pathologically affected mesenteric glands, or possibly absorption of toxin from the intestinal tract.

James Burnett,⁶ of Edinburgh, divided his influenza cases in children into three groups, catarrhal, cerebral and colic. Of the latter he saw six cases, two in each of two families and the remainder isolated. The patients complained of colic pain in the region of the umbilicus, which gradually increased in intensity. On examination, the abdomen was definitely tender in the centre, but peripherally and in the flanks this was not noticed. Vomiting never occurred and the tongue was coated. Partaking of cold fluids increased the pain, but this was not so with hot fluids. There was no diarrhoea, but rather a tendency to constipation. Pain was intermittent, disappearing for long or short intervals, only to return again as severe as before. The temperature remained elevated about one week and gradually fell to normal, never suddenly. The irritative cough, so typical of influenza, was a constant symptom.

The following case-history, from my own practice, presents many points of resemblance to those just quoted from the literature.

CASE 1

J. C., male, aged six years, first seen September 23, 1925.

Family history—Unimportant.

Previous illnesses—Mumps, measles, occasional attacks of tonsillitis.

Complaints—Pain and fever of twelve hours' duration.

Present illness—September 23, 1925. He com

placed at point in lower left side of chest. The temperature was 102°F . He was apparently acutely ill and tender on palpation under left costal margin. The throat was acutely inflamed and slightly swollen. There was no nasal discharge, lungs clear.

September 29th. Temperature, 101°F . Slight tenderness under the left costal margin persisted, but there was no acute pain.

September 30th. Temperature, normal. No pain or tenderness noted.

October 1st. Acute pain in the left side of abdomen, later centering around the umbilicus. Temperature, 102°F . The pain was intermittent, colicky in type, and the patient was unable to turn over. There was no nausea and the bowels were constipated.

Physical Examination—The patient was apparently acutely ill, suffering from considerable pain, colicky in type. He lay with his legs drawn up and refused to move. The tonsils and pharynx were red and slightly swollen. There was no apparent glandular enlargement. The respiratory movements were limited. General abdominal tenderness and muscular rigidity were not at all marked in the area of the umbilicus. There was no particular tenderness over the area of the appendix. The remainder of the examination was essentially negative. The urine was normal. The white blood cells were 7,800 per c mm, with preponderance of polymorphonuclears.

During the afternoon the colic was less severe but the abdominal tenderness was more marked. The colour was poor and the pulse rapid.

Consultation with a surgeon resulted in a tentative diagnosis of acute appendicitis and operation was advised. At the operation the following points were noticed: an acute catarrhal inflammation of the peritonaeum and peritoneal glands, and some swelling and inflammation of the appendix.

Following operation, the temperature remained elevated as high as 101°F and gradually fell to 100°F by the sixth day. During the first few days the patient appeared toxic, acutely ill, and complained a great deal of abdominal pain. Anorexia was marked. These symptoms gradually subsided, and, except for a small superficial wound abscess, his progress was uninterrupted.

I have since heard of several patients presenting histories identical with the above. A number were operated on for acute appendicitis. In one instance, one of twins was operated on, and a week later the other twin developed similar symptoms, but recovered without surgical intervention.

In 1925, Gerald Blake⁷ published a case-history of an adult with intestinal influenza, so called. The symptoms were severe chills, sweating, headache, muscular pains, diarrhoea, and elevation of temperature. A blood count showed 4,400 leucocytes per c mm. There was no evidence of respiratory infection. The author believed that patients with a mild form of this symptom complex had frequently been seen since 1919. He considered the diarrhoea to be of toxic origin, due to some organism which causes infection of the respiratory tract. He thought it the exception rather than the rule for these patients to show nausea.

A Lienheimer,⁸ of Munich, has described a sudden outbreak of alimentary intoxication during February and March. There were sixteen cases with five deaths. The main symptoms were, vomiting, diarrhoea, trembling of the extremities, a cerebral laeve, and no elevation of temperature. Cultures from the faeces were negative. One case was in an exclusively breast-fed infant. They occurred coincidentally with an epidemic of influenza and the author considered them an intestinal form of this disease.

Alfred Alexander,⁹ of Berlin, in 1918 reported eight hundred cases of influenza. Twenty per cent of these patients had intestinal symptoms. In 1921 he described an epidemic of what he termed intestinal grippé. The symptoms and findings were given in great detail. All had diarrhoea with blood in the stools, and many patients were jaundiced. The duration of the illness varied from three days to several weeks. At autopsy the following pathological findings were noted, marked hyperaemia of the alimentary tract, especially in the oesophagus, stomach, ampulla and descending colon, where there were petechiae. In one patient who had icterus, the papilla was markedly thickened and showed a large submucous hemorrhage. The gall bladder was full, its mucous membrane thickened, the liver was enlarged, and the spleen large and soft.

CASE 2

C. P., a boy aged 9 months, who was first seen on January 15, 1927.

Complaints—Colic, loose stools, vomiting, fever and irritability, of 24 hours' duration.

Family History—The mother was suffering from what she described as a "head cold."

Past History—The patient had been breast fed since birth, with the gradual addition of cereals, green vegetables, and potatoes, from the age of six months. On January 8th, cod liver oil had been started, and rapidly increased to a teaspoonful twice daily. He had had no previous illness.

Present Illness—On January 17, 1927, the patient slept longer than usual, and the mother thought he was not well. She reduced the feeding to breast milk only. After the 6 p.m. feeding he passed a loose watery green stool with considerable mucus, and later vomited twice. During the night he had frequent attacks of colic, and was given two simple enemas, which were returned with undigested food and mucus, no blood. Anorexia was not marked.

Physical Examination—The temperature was 100°F . The child appeared ill, was fretful, and objected to examination. The tonsils and pharynx were inflamed and slightly swollen. There was a very slight nasal discharge. Otherwise examination was entirely negative.

Impression—Acute rhinopharyngitis, acute gastrointestinal indigestion.

Feedings were discontinued for twelve hours and

water only given by the mouth. Breast feeding was gradually resumed. It was however several days before the stools were entirely normal and a regular diet could be resumed.

I have presented these cases, not because I believe them necessarily due to influenzal infection, but to serve as examples of what might be so considered. In the first case I thought there was a true influenzal infection giving very definite abdominal symptoms. In the second there are several possibilities. In the first place, it is possible that the intestinal upset may have been due to the rapid increase in the dose of cod-liver oil. This I feel satisfied does occasionally happen. Secondly, there may have been some parenteral infection, leading to an associated food-disturbance. Thirdly, it is possible that the infection may have been of an influenzal type, with gastro-intestinal symptoms.

SYMPTOMS

From a review of the literature it is apparent that only a few of the symptoms are a constant feature of the disease-complex termed "intestinal gripe." I shall rapidly enumerate those most frequently mentioned.

Pain—It is probably present in all cases. Most writers mention pains in the muscles of the neck, back and extremities. However, the more severe symptoms are abdominal. Here the pain is colicky in type, localizing around the umbilicus, at which point the tenderness on palpation is maximal. It is intermittent, and gradually increases in severity as the illness develops. There are many explanations offered for it. James Burnett⁶ thought it might be due to an affection of the intestinal muscles as influenza is noted for its effect upon muscles. Usually in this disease the patient complains of muscular pains in the chest, shoulders and extremities. It also seems possible that the colic may be merely the result of some irritant within the intestine. Lastly, the findings, at operation, of catarrhal inflammation of the peritoneum and mesenteric lymph-glands suggests an easy explanation for this distressing symptom.

Fever—In the majority of cases there is some elevation of temperature, ranging as high as 104° or 105° F., in some instances. Occasionally, however, as in the sixteen cases of Uffenheimer,⁸ there is no pyrexia. Personally,

I should feel very doubtful of any case in which there was not at least some slight rise.

Anorexia—Very little mention has been made of this symptom in the literature. However, after discussing this symptom with several pædiatricians I have gained the general impression that it is marked at the onset of infection and often persists for some time afterwards.

Vomiting—There is a great difference of opinion in regard to this symptom. Many report it as occurring in all cases, and I believe it to be present in most where there is diarrhoea. One author considered it the exception rather than the rule.

Stools—All variations from marked constipation to extremely loose, watery movements with blood, mucus, and even pus have been mentioned by various observers. I believe the younger the patients the more liable they are to diarrhoea. Moreover, I believe it a good rule to regard all cases in which blood and pus are accompaniments of a diarrhoea as bacillary dysentery, until proved otherwise.

Jaundice—Several writers have mentioned this symptom in a number of cases, and one, G. Blake,⁷ directly associated influenza and infectious catarrhal jaundice. At present, it seems very difficult to believe that the cause of these two conditions is the same.

White Blood Cell Count—This has not been given much prominence. I could find but one instance in which it was mentioned, and there it was quoted as 4,400. If the infection is really influenzal in origin, we should naturally assume that there would be a leucopenia. However, I am not sure that this is constant.

Respiratory Features—In some of the cases recorded in the literature no positive findings are mentioned, in the majority, however, there has been inflammation of at least the upper respiratory tract. I have not seen any cases in which this was not present.

ETIOLOGY

The etiology is unknown. It is assumed by most writers to be similar to that of the true influenza, because the symptom-complex of intestinal gripe is usually found when this disease is prevalent.

PATHOLOGY

The pathological findings recorded in the literature are as follows: catarrhal inflammation of the peritoneum and mesenteric glands, swelling of Peyer's patches and the solitary lymph follicles, and occasionally hyperemia and swelling of the intestinal mucosa. One or two observers have recorded extensive intestinal hemorrhages.

SUMMARY

1 Influenza is at times attended by such marked intestinal and abdominal symptoms that numerous observers have come to believe in the existence of a gastro intestinal form of the disease, in which the primary seat of infection is intra-abdominal.

2 This so-called "intestinal gripe" has been more frequently observed in the very young than in the adult.

3 In many instances there has been no obvious involvement of the respiratory tract. Diagnosis has been based on the association with epidemics of influenza, and suggested by the generalized muscular pains.

4 Attention is called to the diagnostic difficulties presented by these cases. Numerous other etiological agents may give rise to similar disease-complexes. Among them bacillary dysentery, frozen milk, and parental infections of all types have been mentioned.

Pseudo or Transient, Arteriosclerosis.—E Moschowitz, New York, reports the case with autopsy of a man, aged 45, who entered the hospital with a typical acute or subacute glomerulonephritis, with signs of marked impairment of kidney function. As the radial arteries felt much thickened a diagnosis was made of acute glomerulonephritis on the basis of an old arteriosclerosis with chronic nephritis. The disease ran a rapid course, and death occurred in three and a half weeks after admissions. At autopsy, a subacute glomerulonephritis was found with an aorta that did not show any gross evidences of arteriosclerosis. Moschowitz says that in the course of acute glomerulonephritis, the radial vessels afford a sensation of thickening so that the clinical diagnosis of "arteriosclerosis" is often made. If the patient recovers, this feeling of thickening disappears a few weeks after disappearance of the increased intra-vascular tension associated with the nephritis. This feeling of thickening is the result of two factors: (a) the hypertension itself, and (b) the hypertrophy of the muscular coat consequent to the hypertension. The second factor is the dominant one. When the hypertrophy subsides, the feeling resembling that of arteriosclerosis disappears. In the case here reported, the aorta was found at autopsy to be normal. A recognition of

5 No typical pathological findings have been recorded.

CONCLUSION

There is no evidence as yet sufficient to warrant us in accepting the existence of a gastro-intestinal form of influenza, in which the primary seat of infection is intra-abdominal in origin. If true intra-abdominal infection with the organism of influenza does occur, it is safer to regard it as a complication or sequela of a respiratory infection. Obviously, however, the whole question must remain an open one until there is a more exact knowledge concerning the micro-organism responsible for influenza.

Treatment for Split Finger Nails.—W W Carter, New York, reports the case of a girl, aged 18, who had a split nail on the middle finger of the right hand, the split had reached almost to the root of the nail and had resulted from an injury to the finger six years before. As the nail grew out, the apex of the slit would remain at about the same place. The adviser her to let the nail grow about three eighths inch beyond the end of the finger and then to return for treatment. He then made a drill from a cambric needle and with this made three opposing holes on each side of the slit. He passed sutures through corresponding holes and drew the edges of the nail as close as possible. The finger was then bandaged for protection. As the nail in growing protruded the distance between two of the sutures, the distal end of the nail was pared and another suture placed near the end of the finger. This process was kept up until the apex of the slit was well beyond the end of the finger. A complete cure was effected in six weeks and after the lapse of three years the nail is perfectly normal—*J Am M Ass*, May 19, 1928, xc, 1619.

GENERAL ANÆSTHESIA IN OTO LARYNGOLOGY FROM THE STANDPOINT OF THE SURGEON*

BY EDMUND BOYD

Toronto

THE purpose of these remarks is to give an idea of some of the mechanical factors which may interfere with the administration of anæsthetics in the more common operations of oto-laryngology and to suggest ways of dealing with them. A few general statements will be added.

There is no reason why anæsthesia should be different in this branch of surgery. There is however an important qualification where the throat surgeon is concerned. He must be particular in having good anæsthesia, because he is working in areas through which breathing takes place, on tissues which are very susceptible, and which vary greatly with the condition of the patient. The safety of the patient and the quality of the operative work, are in great measure dependent upon the character of the anæsthesia. The danger to the patient and awkwardness to the surgeon caused by imperfect anæsthesia are hardly appreciated by the anæsthetist. A state of unconsciousness with or without partial asphyxia, may do for an operation on an extremity but it will never do for an operation on the throat. Congestion of the tissues will make any operation more difficult because of the excessive bleeding. Too deep anæsthesia may ruin a bronchoscopic or œsophageal procedure. What is needed is good anæsthesia to the surgical degree no more, no less, anæsthesia into which the patient has been directly induced in which he has a free airway, breathes regularly and properly, has no undue increase in blood pressure, and his tissues are relaxed and in a state of good tone. There is an art in producing this.

Failures to obtain perfect anæsthesia may be the result of faulty administration. But, a most important cause, and one which is so frequently overlooked, is that of failure to

provide for, and failure to maintain, an adequate airway. Without proper breathing it is impossible to have proper anæsthesia. The throat surgeon is in a position to recognize as they occur, the various causes, and types of obstruction in the airway, and should be ready at any time to help in rectifying them.

An obstruction may already exist in the airway, or it may arise during the course of the anæsthetic from (1) the collection of secretions or blood, (2) relaxation of the tissues, (3) spasm, (4) certain combinations of these factors.

The nose is the natural channel for breathing, and is so used, instinctively, from birth. It at any time, however, the lumen is not sufficient, the individual consciously opens his mouth to make up the deficiency. In the act of going to sleep, when the patient loses consciousness, the mouth closes, and forced breathing takes place through the nose. In this way a state of cumulative asphyxia is set up which, sooner or later, according to the degree of obstruction, awakens the patient. During the induction of an anæsthesia, the same process occurs, except that it is complicated by the anæsthetic, and the individual is prevented from awakening. To continue the anæsthetic under these circumstances is inexcusable. Therefore, in any case of organic nasal obstruction, or when the nose has been packed, it is essential, before beginning, to provide some means of continuing the airway through the mouth. A piece of hard rubber, attached to a string, placed between the teeth at one side, or a mouth gag slightly open, will effect this. Often in infants, and sometimes in certain types of adults, this is not sufficient, because the large and powerful tongue seems to fill the whole mouth and most of the oral larynx. A small, suitably curved airway, placed to reach the lower part of the oral pharynx may be necessary.

In the pharynx there may, occasionally, be large, pendulous tonsils, which are drawn down

* Read at the Academy of Medicine, Toronto, at the joint meeting of the sections of Oto Laryngology and Anæsthesia, February 13, 1928.

in inspiration and act as a ball valve. This may be remedied by holding up one tonsil with a tenaculum forceps.

Saliva may collect in the pharynx, more often at the beginning of the anæsthetic when the ether induction is slow. It may act in a reflex way, causing partial closure of the glottis with coincident shallow breathing or it may collect until there is an actual obstruction. This saliva can be bled out with a tongue depressor, and allowed to run out, by turning the head to one side and depressing the lower side of the mouth and cheek, or, suction may be used. If there is no machine, a reversed rubber syringe will do just as well, but to be of any value, the tip of the suction tube must reach the lower pharynx. The best way, however, is not to allow it to occur. The cause usually lies in faulty administration.

When relaxation sets in, the most common type of obstruction is that caused by the falling back of the tongue into the pharynx. The lower jaw, widely opened by a mouth gag, presses the tongue backwards and makes the condition worse. Some manoeuvre which will hold the tongue forward is necessary, such as, (1) Extension of the head. (2) Holding the lower jaw forward by the chin or by the angle of the jaw. (The pain afterwards is often bitterly complained of by the patient). (3) Holding the tongue forward by forceps, or by any other means. (This has the same objection as in No. 2). (4) The lower jaw held forward by a twisting action of the mouth gag. (5) By a curved metal airway. (This is not altogether satisfactory, because the curve is not right and there is no lifting action).

None of the above methods may be quite satisfactory. The best way is to lift forward the back of the tongue and epiglottis by a spatula, using the upper incisor teeth or the jaw as a fulcrum. It would be very easy to design such an instrument to include an opening at the mouth, with a handle in loop form to surround the nose. In an emergency, the blade of a metal tongue depressor can be slipped down, and the tongue held forward.

A rare accident when using ethyl chloride is to have the epiglottis drawn down and sucked into the larynx, at the beginning of a forcible inspiration. This needs immediate attention, and can be rectified by running the finger over

the back of the tongue and pulling up the epiglottis.

Partial shutting off of the larynx commonly occurs, and occasionally there is a complete spasm. This is usually caused by forcing the ether when the patient will not tolerate the concentration. If the closure is slight, it may not interfere with the patient going under. It is often brought on by administering an ether mixture too soon. The superfluous vapour is very irritating to the surgeon, and for short operations, this mixture might be dispensed with. If the closure is marked, it is better to stop the anæsthetic until the breathing becomes free and regular, then to gradually work up to concentration.

Secretions allowed to collect in the pharynx may overflow, and be drawn into the larynx and trachea, causing at first a certain amount of spasm of the larynx, and later, will, with the addition of mucus be churned up in the trachea and act as an obstruction. There are characteristic sounds associated with this condition from which it is obvious that the patient is not breathing well. Under these conditions it is dangerous to proceed with the anæsthetic. By intubating with a suction tube, this condition might be relieved, but an easier way, and one which may save time in the end, is to let the patient come out far enough to cough it all up. He will then go under readily.

If stenosis, or obstruction by a foreign body, should exist in the larynx or trachea, to such an extent that any extra excitation brings on cyanosis, it is very dangerous to use anything that will excite the patient, or increase the respiratory exchange in rate or volume. Ethyl chloride and ether should not be used. It is in such cases that the induction of anæsthesia by chloroform, given sparingly and carefully is of great value, but the administration in these cases should be guided by the surgeon.

Intra-Tracheal Anæsthesia—This is unquestionably of great use in certain cases. A single tube however, has disadvantages, as a free passage for the return flow must be provided, and it does not prevent secretions or blood from getting into the larynx and trachea. It may, on the contrary, make a nice track for them. The pharynx should be kept clear of any such accumulations. Often the patient is only slightly under, the blood pressure is high, and

bleeding takes place very readily. This is a great disadvantage, especially in a septum operation.

The metal airway, with insufflation tube attached, is a very good substitute. It is simple, easily introduced, provides an airway through the mouth and pharynx, and can be used in many cases with great satisfaction.

Clothing—It is important to see that the patient is suitably clothed. An excess of covering interferes with the natural and proper elimination of heat, and may be of harm to the patient.

The use of the rubber sheet over the eyes seems unnecessary. Capillary attraction between the rubber and the surface will draw up ether over the eyes. Intense conjunctivitis has sometimes resulted. A careful anaesthetist will never allow an excess of ether to run off the mask.

If the breathing becomes infrequent and shallow, it may be due to a condition of apnoea, following too forcible and rapid breathing, or it may be due to respiratory failure.

If artificial respiration be called for, it is essential to watch for any efforts at breathing, and to help them along, always keeping in the same rhythm. Ill-timed action may stop them entirely.

When the anaesthetist is late in starting, it is not fair to the patient to force the anaesthetic, besides, it usually results in poor anaesthesia, which causes greater delay. When the patient is not in a satisfactory condition, it is not fair to the surgeon to tell him that he may start the operation. If there be any departure from the normal, an analysis of the situation is advisable, so that the trouble may be rectified at once.

In conclusion, may I state that the surgeon should know something about anaesthetics, should know what he wants, and how to get it. And in turn, the anaesthetist should know something of the surgical technique of the throat. I can think of no better preliminary training for an anaesthetist than an internship, or its equivalent, on a throat service. He would get an idea of the anatomy, physiology, and pathology of the breathing passages. He would become familiar with the ordinary manipulations on the throat. He would learn the mechanics and dangers of anaesthetics, how awkward it is to work with poor ones, and how different it is to work with good ones. He would then be in an advantageous position to acquire the art of the perfect anaesthetist.

ANÆSTHESIA IN NOSE AND THROAT SURGERY, FROM THE STANDPOINT OF THE ANÆSTHETIST*

BY SAMUEL JOHNSTON, M A, M D, F A C P

Toronto

THE day has passed when a nose and throat operation is looked upon as a trivial affair. Experience has taught us that a patient about to undergo an operation on these parts, or even on the tonsils alone, must be as carefully prepared as for any major operation. Especially is this true with regard to adult patients, to whom the surgical shock may be as severe as in any so-called "major" operation. This is also the case from the standpoint of the anaesthetist.

The anaesthetist has before him one crucial problem, the safety of the patient, and to this end should co-operate with the surgeon in

administering an anaesthetic with a surgical degree of narcosis and necessary muscular relaxation. There is no branch of medicine in which personality counts so much as in anaesthesia. This applies not only to the anaesthetist's attitude to the patient, but also in his dealings with the surgeon, physician, or any one with whom he is working. He should be possessed of a mind open to any valuable suggestion offered, or to fair criticism made, without feeling any resentment.

Previous medication for adults is an important factor in nose and throat anaesthesia, unless of course, there is some contra-indication to its use. I have found it of great assistance, especially with nervous patients. Morphine $\frac{1}{4}$ gr, with atropine $\frac{1}{150}$ gr or $\frac{1}{200}$ gr ad-

* Read before the combined Sections of Oto Laryngology and Anaesthesia, Academy of Medicine, Toronto, February 13, 1923.

administered one half hour before operation, or morphine $1\frac{1}{2}$ gr, atropine 1/150 gr, hyoseine 1/200 gr, administered three quarters of an hour previous to operation meet the requirements of most cases.

The induction of anæsthesia is much the same for all types of surgery. Most anæsthetists induce anæsthesia with ethyl chloride and sustain this with ether. Some use ether or a mixture of chloroform and ether, while others use nitrous oxide and oxygen for induction. There are some cases in which nitrous oxide and oxygen should be given throughout, as diabetes, pulmonary tuberculosis or acidosis. It is not the most satisfactory anæsthetic for routine work, though it is used considerably in some clinics. The most important points to be considered in the use of nitrous oxide and oxygen are the skill of the anæsthetist and the complete co-operation of the surgeon. However, unless contra-indicated, the ideal anæsthetic for sustaining narcosis in nose and throat surgery would seem to be ether.

While one should never allow himself to be hurried in the induction of anæsthesia, one finds that the more quickly he can get a patient into the surgical stage of anæsthesia, with safety and comfort, the better will be the type of anæsthesia. This is specially important in nose and throat operations for the following reason, the longer you take to anæsthetize your patient, the more saturated all the tissues of the body become, and the reflexes will be correspondingly slow to return, whereas, the cough reflex should return as soon as the operation is completed. If the patient is saturated, he may inspire some of the blood and mucus, laden with all kinds of bacteria from the nasal and buccal tracts, and the results may be disastrous, as exemplified in lung abscess or pneumonia.

Once surgical anæsthesia has been established, the insufflation and suction method is generally used. Care should be taken to keep the suction tip as near the median line as possible, as it is very annoying to the surgeon to have it continually in his way. Another thing to be avoided is the uvula, if the suction tip comes in contact with the uvula, it quickly produces œdema.

Insufflation anæsthesia is best accomplished by passing a catheter through the nose to the

nasopharynx. Care should be taken not to have too great pressure, as blood may be forced into the trachea. In nasal operations, where the insufflation method is employed, a metal mouth anway is used, to which the insufflation tube is attached.

Many nasal operations are better done with intra-tracheal anæsthesia. Here, some experience is necessary before the catheter can be passed with ease. Complete relaxation must precede this method or difficulty on account of spasm will be experienced in introducing the laryngoscope. A double catheter may be used with advantage, attaching the insufflation tube to one and leaving the other for expiration. When the two tubes are used, it is advisable to pack some gauze down around these tubes, to prevent any possibility of blood or mucus entering the trachea. The second tube tends to make intra-tracheal work much safer. It is better to have the exhaust tube a size larger than the insufflation tube. This second tube has another advantage in prolonged operations, as a long rubber tube can be attached to it and thus the ether is carried completely away from the field of operation. In this way, the surgeon is not hampered by the ether being blown into his face. McGill, of London, has devised a tube which consists of two separate tubes joined together about two inches from the distal end, the supply tube extending an inch further than the exhaust tube. This has an advantage over the two single tubes, as often, after one tube is passed into the trachea, a spasm is caused which makes the introduction of a second tube difficult and sometimes impossible. One must keep in mind, however, the dangers of the intra-tracheal method. Experience has shown that a slight degree of positive pressure is not dangerous, but high or long-continued pressure may result in serious reflex disturbances in the lungs, and deleterious effects upon the circulation, depending upon the reserve power of the right ventricle. Positive pressure sometimes produces numerous disturbances in normal circulation in the lungs, such as reflex compression of the lung capillaries (Sauerbruch).

In bronchoscopic work, difficulty is sometimes encountered in sustaining smooth inhalation anæsthesia. When the bronchoscope is in position, an insufflation tube cannot be passed,

owing to obstruction of the view, so that a straight metal tube must be resorted to, which is attached to the insufflation tube and the current of air is directed into this tube. Although this is quite easy to accomplish for short operations, it is much better in prolonged cases, such as when searching for a foreign body, to induce and sustain anaesthesia *per rectum*.

It is impossible for a surgeon to do good work in nose and throat operations, unless the anaesthetist is able to maintain complete relaxation of the muscles of the throat during operation. This also lessens the danger of hæmorrhage. In this type of operation, the narcosis should be of such a degree that the palate and faucial arches are flaccid and there should be no reflex spasms of the pharynx. In order to obtain this, one must have free ventilation of the lungs from start to finish. One must recognize what free breathing is. Too often the anaesthetist is satisfied if the patient is snoring or making a noise with each respiration, or if the colour is fairly good. This is not sufficient. One must have a perfectly free airway with the colour better than normal. If this care is not taken, one may have saliva and mucus, and, gravest of all, partial asphyxiation instead of anaesthesia.

Having regard to the essentials of anaesthesia in nose and throat surgery, we now come to a few minor details. The patient can be placed in almost any position convenient for the surgeon, though the present day consensus of opinion is, that the recumbent position is the most desirable. It is essential that the patient should be made comfortable previous to the

administration of the anaesthetic, allowing him to go to sleep in any desired position. It is an easy matter to re-arrange this after he is anaesthetized.

On the completion of the operation, the patient should be placed on his side, so that if there is any oozing, it will drain from the angle of the mouth. Also in this position, the tongue is not so likely to fall back and obstruct the breathing. Another thing, a patient should not be allowed to leave the operating room with damp clothing, and some competent person should remain constantly with him until consciousness has returned.

After nasal operations where there is packing in the nose, either a mouth-gag or metal airway should always be placed in position until the patient has recovered sufficiently to breathe naturally. Personally, I prefer the airway, as it prevents the falling back of the tongue and lessens the danger of injury to the teeth.

In conclusion, may I say that, though anaesthesia has travelled a long, hard road since Voltane said, "A physician is one who pours a drug of which he knows little into a body of which he knows less," we do feel encouraged to go on in the light of present day achievements in this art. Its future development can only be left to the imagination when we take into account the vast amount of research work being done along this line. It would seem that the age of "blunder and luck" has passed away forever, and we have reached the goal of safe anaesthesia for surgery.

Endometrial Tumours in Abdominal Scars—Endometriosis occurs in abdominal scars by direct transplacental migration of endometrial cells, which after a varying latent period form small tumours in this new habitat. The frequent occurrence of these lesions after uterine suspension or fixation of various types suggests the advisability of care in using traction sutures perforating the uterine wall as a method of elevating the uterus, and of protecting as thoroughly as possible the wound edges and peritoneal surfaces when the uterus is incised or punctured by instruments. Even salpingectomy with resection of a wedge of uterine muscle at the cornu may scatter viable endometrial cells which may become implants. Implantation endometriosis in caesarean wound scars is remarkably rare and suggests lower viability and a slighter tendency toward growth in the endometrial cells during pregnancy than during the non-pregnant state.—Marion Douglas, *J Am M Ass*, June 9, 1928.

Menstruation and Menstrual Disorders—Emil Novak, Baltimore, urges caution in the therapeutic application to human patients of the results recently obtained through studies in animals, valuable as these studies have been. His own results with folliculin therapy have left him doubtful of its efficacy, and this seems to have been the experience of others as well. In cases of hypofunction of the ovary, particularly in amenorrhœa, it would be surprising if follicle injections in themselves were successful in restoring menstruation. It is much more rational to mimic what is believed to be the normal sequence of events, and to give a series of injections of follicle substance, followed by a series of injections of lipid containing corpus luteum extract. Novak's only encouraging results have been with this plan of treatment, which he believes to be far more rational than the injection of either follicle substance alone or corpus luteum extract alone.—*J Am M Ass*, Feb. 4, 1928.

A NOTE ON THE OUTBREAK OF RABIES IN THE KINGSTON DISTRICT

By W D HAY, M A, M D,

Assistant Professor of Pathology, Queen's University, Kingston

IN the June number (1928) of the *Public Health Journal* Drs Seymon and Bell gave a brief review of the rabies situation in Canada. The Dominion was entirely free of the disease from 1917 to the fall of 1925 when at the close of the hunting season it appeared first in the Ottawa district. During 1926, cases occurred in the counties of Russell, Dundas, Lanark, Renfrew, Grenville and Leeds. Then another outbreak of the disease took place in the Sharbot Lake district in the northern part of the County of Frontenac, in the autumn of 1927.

On February 12, 1928, a farmer in the Perth Road neighbourhood, thirty miles north of Kingston, reported to the Veterinary Inspector that a strange dog had appeared in the vicinity, and that it was roaming from place to place fighting with every dog it encountered. The dog was shot and the head was sent to the Kingston Branch Laboratory where the brain was found to contain numerous Negri bodies. It is of interest to note that the dog had broken most of its teeth during its period of madness.

The Federal Inspectors investigated the case but they were unable to find the owner until a month later when several contacts had died of rabies. Although no mad dog was known to have entered the City of Kingston, three animals developed symptoms of rabies on the 14th and 15th of March. One was proved to be positive on laboratory examination. The second left the city and killed a number of sheep on a farm about five miles west of Kingston. One sheep which was lacerated about the head developed rabies a month later and its brain was found to contain numerous Negri bodies. The third dog showed symptoms of the dumb type of the disease. It died, and was destroyed without laboratory examination.

The Veterinary Inspectors at once proceeded to induce the various township authorities concerned to pass quarantine regulations. The co-operation of the Kingston police soon checked the spread of the disease in the city, though several dogs developed symptoms of rabies

during April, and two were proved rabid by laboratory examination. The conditions, however, were not so satisfactory in the country districts. The quarantine regulations were passed by the various township councils, but, it was difficult to enforce them. The Federal Inspectors did their utmost to get the co-operation of the people, but it was not until the outbreak became really serious that they received the necessary assistance.

One child was badly bitten on the face by a dog which was proved rabid by microscopic examination. Treatment was begun four days afterwards. Twenty-one doses of vaccine were given and the child remained well. About the middle of April the disease appeared in a number of herds of cattle. Several farmers lost heavily in this way. The head of one animal from each herd was sent in for laboratory examination, and in five cases they proved positive.

One interesting example of the way by which dogs spread the disease may be given. A collie from the Kingston district entered the town of Napanee one evening. A lively fight occurred on the street, and a month later seven dogs died of rabies, four of them came from residences within a hundred yards of where the fight took place.

The important points about the epidemic were first, that the disease gained widespread distribution before the co-operation of the public was enlisted sufficiently to have the dogs effectively tied up. No case of hydrophobia occurred in the human subject. This was probably in large part due to the efficient use of vaccine, prepared according to the Semple method by the Connaught Laboratories and distributed free by the Ontario Department of Health. Fifty persons who had been bitten, or had been in contact with rabid animals, received treatment at the Kingston General Hospital. No severe reactions followed the use of the vaccine, though a few individuals complained of slight malaise and urticaria between the seventh and tenth days after the commencement of the treatment.

Case Reports

CASE OF SPONTANEOUS RUPTURE OF THE HEART*

By JAMES MILLER, M.D., D.Sc.,

Kingston

Cases of rupture of the heart with consequent hæmopericardium are by no means common. They may be divided as regards their causation into traumatic and spontaneous. The former are the more frequent, and are due to penetrating wounds by knife or bullet, or to crushing of the chest. In the former the injury to the heart may be anywhere, in the latter it is usually a tear in one of the auricles.

Spontaneous rupture may be due to various causes. Very rarely, it may occur in a practically healthy heart. We have seen it as a result of overdistension in sudden, violent exertion, and also during the administration of an anæsthetic. In both instances it was the right auricle which gave way. In most cases, however, the heart muscle is the seat of some gross pathological change. The commonest of these pathological conditions is degeneration, the result of obstruction to the lumen of the coronary artery. Usually the coronary artery is the seat of atheroma with narrowing of the lumen and thrombosis on a diseased patch. Only in very rare instances is the obstruction due to embolism. The degenerative changes which occur are fatty degeneration, necrosis and fibrosis, occasionally complicated by an aneurysm of the heart, rupture occurring in the sac of the aneurysm.

In virtue of the fact that it is the anterior descending branch of the left coronary which is most commonly the seat of atheromatous disease, the rupture is usually found in the distribution of this artery, *i.e.*, on the anterior wall of the left ventricle near the apex. It is also in the area supplied by this vessel that aneurysms of the heart wall are usually found. We have seen one case in which the rupture occurred in the posterior wall of the left ventricle, *i.e.*, in the area supplied by the

posterior descending branch of the left coronary.

Less frequent, as a cause of rupture, is acute inflammatory disease of the myocardium. We have seen it as the result of an embolic abscess in the wall of the left ventricle, in a case of acute osteomyelitis in a child.

Lastly, as a cause of spontaneous rupture, there is fatty infiltration of the heart wall. In such a case the rupture is found in the anterior wall of the right ventricle. Robert Murray figures such a heart in his text-book (p. 262) and the underlined case is probably due to the same cause.

CASE

The case was that of a woman, aged 77, who was admitted to the Kingston General Hospital on October 3, 1927. She had always been well until two years previously, when she had a stroke. After this her right side was crippled, and she had a good deal of difficulty in getting about. Three days before admission she had complained of severe pain over the stomach and in the left hypochondrium.

Examination at the time of her entrance to hospital showed some irregularity in the action of the heart due to extra systoles. The heart was slightly enlarged, the apex beat being in the fifth interspace, $4\frac{1}{2}$ inches from the mid-sternal line. The pulse was 88, and the blood pressure, 160 systolic, 80 diastolic. The vessels throughout were thickened. Pain was still present at the time of admission and there were two subsequent anginal attacks, the first on December 14, 1927, the second on the day of her death.

At four p.m., on February 28, 1928, the patient was seized with intense agonizing pain in the region of the upper epigastrium. She became restless, cyanosed and faint. There was vomiting, and the pulse was feeble, rapid and irregular. In spite of treatment, she sank into unconsciousness and died at 8 p.m. on the day of the attack.

The case, clinically, was thus one of arteriosclerosis and cerebral hæmorrhage, exhibiting

* From the Departments of Medicine and Pathology, Queen's University, Kingston.

a series of heart seizures diagnosed as due to blocking of branches of the coronary artery

The post-mortem examination was performed the morning after the patient's death, and showed the following

The pericardial sac was filled with fluid and clotted blood. A small ragged tear was present in the anterior wall of the right ventricle near the apex and close to the interventricular septum (Fig 1)

FIG 1—View of the heart lying on its posterior aspect, taken from the right. The wall of the right ventricle is loaded with fat. An oblique incision has been made through the muscle and below this is the ragged tear to which the arrow points

The heart weighed 450 gm. All the cavities were dilated and contained blood clot. The wall of the right ventricle was loaded with fat and showed, microscopically, penetration of the adipose tissue between the bundles of the muscle fibres (Fig 2)

FIG 2—Low power view of the wall of the right ventricle, showing bundles of muscle fibres broken up by infiltration with fatty tissue

The left ventricle contained a recent thrombus attached to the interventricular septum near the apex. The muscle had a mottled appearance, and showed, microscopically, large fibrous scars, with bundles of muscle fibres in a state of fatty degeneration and necrosis (Fig 3)

FIG 3—Low power view of the wall of the left ventricle, with fibrous scars (pale areas) and bundles of muscle fibres showing fatty degeneration and necrosis

The mitral and aortic valves manifested a condition of chronic endocarditis

The coronary arteries were thickened throughout, and the anterior descending branch showed a thrombus blocking its lumen. Microscopically, there was thickening of the intima, with fatty change and fibrillation of the internal elastic lamina

There was dropsy of both pleural sacs, and partial collapse of the lungs, which showed evidence of old healed tuberculosis

The liver, spleen and kidneys showed chronic venous congestion. There was a small parovarian cyst on the right broad ligament, and the gall bladder contained a small mulberry stone

COMMENT

We have, then, a case of arteriosclerosis with a history of a cerebral hæmorrhage, developing a series of heart attacks, associated with pain in the epigastrium, in one of which the patient dies. Blood is found in the pericardial sac, and a small tear is present in the anterior wall of the right ventricle. The heart muscle in the near neighbourhood shows fatty infiltra-

tion, so that it may be assumed that the rupture was due to this somewhat rare cause. There were, in addition, obstruction to the descending branch of the left coronary, and fatty degeneration, necrosis and fibrosis of the muscle of the left ventricle. Thus, all the conditions were present which usually accompany rupture of the left ventricle, and the curious thing was that the heart did not burst at this point. The actual point of rupture was an area of muscle weakened by invasion with adipose tissue. The violent and irregular contractions of the muscular organ, accompanying blocking of a large branch of the artery of supply, no doubt precipitated the rupture at the weakest point, *viz*, the anterior wall of the right ventricle.

The case emphasizes the ease with which cardiac pain may be mistaken for gastric pain, especially when, as in this instance, the pain was accompanied by vomiting. We have seen in a case of the kind a diagnosis of acute indigestion made, and death put down to this cause.

DIABETES, ARTERIOSCLEROSIS, AND GANGRENE*

By EDWARD H. MASON, M.D.,
Assistant Professor of Medicine,
McGill University,
Montreal

At this time it seems appropriate to bring before the members of the profession, and especially before the surgeons, the results that are being obtained in the treatment of the gangrene which so frequently occurs in diabetics. Formerly, the occurrence of gangrene in the diabetic resulted in surgical interference of a radical nature in a large percentage of the cases. Today, the possibility of avoiding such interference is much greater.

During the past two years, twenty-four cases of diabetes mellitus with gangrene have been admitted to the Metabolism Clinic of the Royal Victoria Hospital. Two of these cases died within a few hours of admission. Of the remaining twenty-two cases, fourteen had extensive gangrene of one foot, while in eight the gangrene was confined to one or more toes. In five

of the fourteen cases that had gangrene of a foot complete cure of the gangrene was obtained by medical means alone, the remaining nine having amputations. Of the eight cases that had gangrene of one or more toes a complete cure without surgical interference was effected in five, while the other three had a local amputation only of the toe affected.

In this small series 36 per cent, therefore, were cured without surgical interference when the gangrene involved the foot, and 63 per cent were likewise cured when the gangrene involved one or more toes only.

These results I consider to be representative of what can be done with gangrene in the diabetic, and indicate the conservative attitude that the profession should adopt in dealing with such cases.

CASE REPORT

The present case is that of a woman of sixty-one years who was primarily admitted to the Royal Victoria Hospital on February 2, 1927. Three months before admission when cutting a callus on the sole of the right foot blood was drawn. Shortly, swelling and pain in the part appeared. Gradually the swelling involved the whole foot as well as the lower third of the leg. In a few days the whole limb was reddened, warm, and tense.

Upon admission, there was a discharging ulcer on the plantar surface of the foot, and the cellular planes were extensively infiltrated with pus. Lymphangitis extended well up the leg. An incision was made, and through and through drainage established. Examination of the urine revealed marked glycosuria, a finding previously unknown to the patient. With the administration of insulin the blood sugar rapidly fell to normal, and the spreading infection became arrested (see Table I). Subsequently it was necessary to establish more complete drainage, but the foot healed progressively.

This involvement of the right foot was not true gangrene, but extensive infection. Since palpable arterial pulsation was present in the foot I was optimistic from the onset as to the outcome.

Leaving the hospital in April, 1927, our patient continued to follow her diet and take her necessary forty-four units of insulin per day until August. Then for financial reasons she

* Presented at a meeting of the Montreal Medico-Chirurgical Society, March 16, 1928.

was forced to discontinue the insulin. The diet was continued.

At Christmas time prickling sensations developed in the sole of the *left* foot. A gangrenous patch rapidly developed upon its plantar surface, and the second toe became discoloured. When admitted on January 22, 1928, the whole foot was swollen and there was a purulent discharge from the large gangrenous patch upon its plantar surface. The second toe was almost black, and the inflammation extended well up the leg.

Examination indicated that the circulation of this leg was much impaired. No palpable pulsation in the foot could be felt, and an x-ray showed rather extensive calcification of the arteries, both in the leg and in the foot. The findings were so formidable that the surgeon in consultation advised immediate amputation (See photograph).

With strict control of the hyperglycæmia and glycosuria immediate improvement followed. This improvement has continued progressively until the plantar gangrenous area was almost replaced by healthy granulation tissue and the dead toe ready to drop off.

TREATMENT

In the treatment employed, rest and warmth, with strict control of the diabetic condition through diet and insulin, were regarded as essential. Patience and persistence came next. Moist dressings should be avoided in all cases of diabetic gangrene. As accessories we have used passive daily elevation and lowering, and in some cases voluntary exercise. Ultra-violet light, both general and local exposures, have also been employed, but we do not consider that these accessories were of fundamental importance in the results obtained. That healing and the formation of granulation tissue must depend upon the development of collateral circulation would seem evident. That such compensatory circulation can develop with time, even when the larger vessels of the leg and foot show marked calcification, is the lesson to be remembered from our experience of the past two years.

Plantar surface of the left foot, showing large gangrenous area which healed progressively by medical treatment. (Photo on February 12, 1928)

A CASE OF CHORIOEPITHELIOMA*

BY ELEANOR PERCIVAL, M.D.

Montreal

Mrs McK, aged 34, was admitted to the gynaecological service of the Montreal General Hospital on July 6, 1926, complaining of vaginal bleeding which had continued for ten weeks. Her previous menstruation had been normal. She had been pregnant five times, the first, middle and fifth pregnancies ending in abortion between the third and the fifth months. The last miscarriage occurred at five months, in December, 1925. Following this, she had amenorrhœa, until the bleeding which caused her to seek advice began in May, 1926.

On admission, the uterus was found to be the size of a three months' pregnancy, and characteristic small, white, cystic masses were noted in the bloody discharge. Under anæsthesia, the uterus was explored with the finger and a cupful of small cysts removed. Pathological sections showed a benign hydatid mole.

The patient menstruated normally in July, but on August 16th, bleeding recurred, and continued until her re-admission on September 13, 1926. A curettage done two days later showed the uterus to be three inches deep, and with the curette a small amount of normal endometrium was obtained. Three weeks after this, bleeding began again, but this time it was much more profuse than formerly. She was re-admitted on November 29, 1926, and a hysterectomy performed. Sections of the uterus showed no abnormal tissue.

From this time on, the patient gradually failed, losing thirty-three pounds during the following nine months. In September, 1927, she was admitted for the fourth time, complaining of vomiting, palpitation, pain in the right lower quadrant, and sleeplessness. Examination showed a markedly dilated heart, normal chest, the liver enlarged to three fingers-breadths below the costal margin, and the pelvis filled by large cystic masses which were movable and about the size of two large oranges. The pelvic mass did not suggest malignancy, nor were there any nodules palpable in the vagina. The patient gradually failed and died on September 22, 1927.

At autopsy, hæmorrhagic, friable masses were found in the liver, which was greatly enlarged, also on the right anterior chest wall, at the base of each lung, on the mucosal surface of the jejunum, and in the pancreas. The pelvis and vagina were clear of these hæmorrhagic masses, but two large benign multilocular cysts were present.

FIG 1—Section from metastatic growth in liver showing the two types of cells.

Microscopically (Fig 1), the tumour masses were made up almost entirely of broad, irregular, anastomosing strands of the two types of chorionic epithelium. The Langhans' cells were distinguished by their smaller, more regular form, with clear protoplasm and fairly sharp cell outline, while the syncytial material formed solid areas, which stained more deeply and in which numerous nuclei were embedded. The cells grow diffusely with no orderly arrangement. The stroma and newly-formed blood vessels were inconspicuous. In one section, tumour material was seen within the lumen of a vein (Fig 2). No villi were seen in any of the sections. In the Langhans' cells, mitotic figures could be seen, and it will be noted that the Langhans' cells were not sheathed everywhere by syncytium as in the normal placenta.

The tumour was, therefore, a rapidly growing malignant one, developing from the epithelial elements of young placental tissue—a "chorioepithelioma." A ripe placenta, i.e., one with mature villi, never becomes malignant.

* From the Gynaecological and Pathological Services of the Montreal General Hospital.

COMMENT

Chorioepithelioma may follow hydatid mole, abortion, or pregnancy. About 8 per cent of all hydatid moles undergo malignant degeneration, but a history of a mole is given in about 50 per cent of cases of chorioepithelioma. Women who have had five or more pregnancies are most susceptible to the growth. The average age incidence is 33 years.

The tumour was first clearly understood and accurately described by Marchand in 1895. He identified it as being derived from both the

FIG 2—Section from the pancreas showing tumour in a vein.

Nitrites for Seasickness.—Drs J Frank Pearce and Daniel B Hayden announced that doses of from 0.2 to 0.3 gm. (3 to 5 grains) of sodium nitrite every two hours relieved eight persons of such symptoms as ocular nystagmus, vertigo, ataxia and nausea within four hours. Moreover, the patients did not suffer any recurrence of the symptoms. Now further support for this method comes in a note by Dr A Sellheim of Leningrad to the *British Medical Journal*. He found that a single drop dose of a 1 per cent solution of glyceryl trinitrate (nitroglycerin)—which has the physiological action of nitrites—kept one patient from turning sick. Another person who was sick was able to take dinner twenty minutes after swallowing 0.65 mg daily. Other patients were protected from seasickness or cured of it by one dose of two drops of a 0.5 per cent solution placed directly on the tongue. Here apparently is a method independently developed in two widely separated places. The clinical evidence seems perhaps less empiric than for many of

Langhans' and syncytial layers of the placenta, and traced its etiological relationship to the hydatid mole.

Marchand describes two separate types of tumour. The first is the typical form, which tends to mutate the trophoblast of the early months. This is a very malignant type that tends to metastasize widely, dissemination occurring by the blood stream. Our case is a good example of this "typical" chorioepithelioma. The second variety is the atypical one, in which the Langhans' cells are less numerous, and syncytial masses fewer, but there is a diffuse infiltration of the maternal tissues with chorionic wandering cells. The tumour is not nearly so malignant, cures from amputation and hysterectomy are on record.

Normally, both the Langhans' and syncytial layers have a tendency to grow outward into the spaces between the villi. The syncytial covering becomes heaped up, forming polypoid processes, which may break off, lie free in the intervillous spaces, or even enter the blood stream and be carried to distant organs. However, once pregnancy is over these cells rapidly disappear. In chorioepithelioma, on the other hand, the normal destruction of these cells does not occur. Hence, as in the case cited, the uterine tumour may be very small or even entirely expelled with the placenta, while widespread metastases are present.

the remedies for seasickness heretofore available—*J Am M Ass*, April 28, 1928

"I say, without the slightest fear that I may be overstating my case, that there is no profession which is more exposed to the temptation to forget honour, humanity, and kindness than the medical profession, and none in which the exploitation of human suffering is easier. Yet there is none in which the temptation is so triumphantly withstood. Let this be remembered by the public when they feel inclined to sneer at medical etiquette and to speak of it as if it were a code for maintaining selfishness and enrichment. Medical etiquette is the salvation of the patient. It is the one thing which stands between him and the dangers of exploitation. It is what makes him and his sufferings hold the dominant part in the dread dramas of pathology."—John St Loe Strachey, *The River of Life*

Editorial

OF THE MAKING OF BOOKS THERE IS NO END

ONE of the pressing problems facing the scientific world of to-day is that involved in the extraordinary number of scientific publications issued annually. The vast majority of these are papers or short contributions giving the results of investigations in the various fields of science, including medicine, pathology, bacteriology, physiology and biochemistry, in which the annual output is ever on the increase. This ever-increasing output is not the same in all departments, but in all during the last fifteen years it has very greatly exceeded the annual rate of increase in each of the preceding twenty years, when the total number of papers published was not more than a few thousands in all lines.

What it is now may be inferred from an estimate of the number of scientific journals annually published, made by Dr Jocelyn F Thorpe and given in his address as President of the Chemical Section of the British Association at the meeting in Oxford in 1926. This estimate was 23,000. If in each subject on the average ten papers, a conservative estimate, appear, then more than 200,000 scientific papers are published annually. What this signifies concretely for chemistry is indicated in Dr Thorpe's statement that to the joint library, in Burlington House, of the Chemical Societies of England, 800 volumes of chemical journals are now added annually. "The mind is appalled at the prospect," he says, "that will confront civilization in a century from now, unless some general method of curtailment of publication is adopted and observed. The space occupied by our ever-increasing libraries will rival that of the cemeteries which threaten to cover the earth eventually. The cemetery problem can be solved by cremation. Is it too much to hope that a judicious exercise of cremation may also be applied to our libraries?"

In medicine and the allied sciences the publication problem is as threatening as it is in the other sciences. Even to-day the

number of papers published annually in medical journals is so large as to defy even approximate estimation, but it is certainly well up in the thousands. Indeed, on insulin alone, according to a statement made last year at a meeting of German pharmacologists, more than 5,000 have appeared since 1924.

That this enormous output is excessive is admitted generally. Professor Frederick von Mullen, the eminent clinician, two years ago severely criticized the editors of the German medical journals, charging them with publishing anything and everything that was offered in the form of contributions, whether or not these were worthy of appearing in print, thus loading the record with a vast mass of inferior stuff.

Where is this all to round up? Will these myriads of papers be read, noted and referred to ten years from now? Or will they be remembered like "the snows of yester year?" To give attention in the years to come to a multitude, perhaps thousands, of papers on a single more or less limited subject will result in the breeding of scientific book worms, specialists who "know more and more about less and less", and whose influence on the general trend of knowledge in the sciences, in which they are enlisted, will tend to have an ever decreasing effect.

One of the most influential factors in the promotion of this enormous output of publication, so far as America is concerned, is the status accorded in the universities to members of the staffs based on the number of their publications each year. It would appear that no junior teacher has any chance of promotion who does not publish at least one scientific paper a year, and promotion is assured for one who has many papers to his credit, whether they be important or trivial in value. In consequence, there is an ever increasing tendency amongst the younger generation of scientific workers to multiply their papers by publishing the results of a single investigation of a subject

in a number of separate contributions, each with the same title, but labelled separately by the numerals I, II, III, IV, and so on. It is not only junior scientific workers who are prone to multiply in this and other fashions the number of their publications. It is disturbing to read in a recent eulogy of a senior scientific worker that he has published more than two hundred papers! If every scientific worker aimed at publishing one hundred papers the result would be appalling in a few years.

The old saying, "Of the making of books there is no end," was expressed when all the written word was in the form of manuscript, and manuscripts were countless in the libraries of the ancient world. The Arabs in the eighth century burnt the library at

Alexandria, the Moslems did the same in the fifteenth century for the library at Constantinople, and the Goths, Vandals and Huns played a like part in their invasions of Italy before the sixth century. In consequence, of the ancient Greek literature not more than ten per cent has survived. Much that was of inestimable value and much that was worthless have thus gone into oblivion. We cannot hope, even if we were so minded, to have hordes of barbarians invade our Western world and, thus, in their rude fashion, solve our menacing library problems.

How about a League of Nations' Committee to suggest a code of ethics which will impose a severe circumspection regarding publication in science?

A. B. MACALLUM

THE NEW WORSHIP OF THE SUN

THE sun has at all times and in all climes been an object of veneration. Indra, Ammon Ra, Zeus, Jupiter, Apollo and Wodin are all, probably, personifications of the king of the heavens, and, as a merely physical object, the sun has been worshipped by native tribes in southern United States, Mexico and Peru, and still is, to-day, by the Parsees, the modern representatives of the Zoroastrians. This need cause no wonder. The sun is the most striking and splendid single object in nature. It is the source of light and heat, it is the dispenser of health and happiness, it is the giver of life itself. All will admit that the sun is essential to the welfare and continued existence of all living creatures, whether animals or plants. Yet, while this fact has been patent for long, it is only recently that the explanation of the fact has been dawning. The story of the sun, in this its latest phase, is as entrancing as the plot of any novel, and we are only on the threshold of our knowledge.

As an evidence of the wide interest that the subject is beginning to evoke among all classes, reference may be made to the "Sunlight and Health Number" of the London *Times*, which appeared on May the twenty-second, last. This is a publication of forty large pages, twenty-two of them being devoted to articles by recognized authorities

on different aspects of the subject. The words of the *Times* in the introductory editorial are so happy and appropriate that they must needs be quoted here.

"The modern use of sunlight as a healing agent is a rediscovery of knowledge which at one period of history was widely disseminated. Nevertheless, the modern use of sunlight is entitled to rank as in some way a new departure, for it is based on observation and study which belong peculiarly to the present stage of the evolution of science. The story is among the most interesting and romantic in the annals of medicine. Some ten years ago, when Europe was engaged in the final struggles of the Great War, the discovery was made that the lack of animal fats, which had resulted from the enormous consumption of fat in the manufacture of high explosives, had reduced human resistance to a number of diseases. Rickets was widespread throughout the Central Empires, tuberculosis was taking a greatly increased toll of life in all the belligerent countries. When the war ended efforts were made to supply fats, in the form of cod-liver oil, to the children of Vienna and other stricken cities, and then the strange observation was made that this supply, though apparently essential in the winter months, became less necessary as summer

advanced The first glimmerings of the truth were received that animal fats are, in some respects at any rate, an equivalent of sunlight in the balance of health, or, in other words, light is food Only eight years have passed since the first announcements of the discovery were made, yet in these eight years a new science has been established and a new therapy introduced "

Attention was directed anew to the work of Dr Edward Mellanby, who, in 1915, had made the discovery that rickets is a "deficiency disease," thus bringing it into the same category with scurvy and beri-beri The trouble lies, as all now know, in the lack of a substance known as "Vitamin D," which Dr Mellanby showed to be soluble in fats and oils

When the war ended a commission was sent to Vienna by the British Medical Research council, in collaboration with the Lister Institute of Preventive Medicine, consisting, with others, of Drs Harriette Chick, Elsie Dalyell, Helen Mackay and Miss E M Hume, which investigated the subject of rickets for about three years Then it was that the beneficial effects of sunlight in this disease were laid bare, and the conclusion was reached that in some unknown manner the rays of the summer sun supplied the deficiency for which, in winter, cod-liver oil was a specific The questions were then asked—"Is cod-liver oil, then, a sort of bottled sunlight?" The cod is a deep-sea fish, living in northern waters, remote from the rays of the sun "How can sunlight reach it?" In due time came the answers On the surface of the sea are countless myriads of animalculae, known as plankton, which have the power of absorbing the sun's rays, much as blotting-paper absorbs ink These minute creatures form the food of the squid, which in eating them acquires their treasure store of light In turn, the squid is eaten by the cod, and so, by two steps, the actual rays of the sun become stored, to become potential for good, in the liver of the cod

While these researches were going on, Dr. Huldchinsky, of Berlin, also working on rickets, made the remarkable discovery that if, instead of giving cod-liver oil to a child affected with rickets, he gave it a bath in the light from a quartz mercury-vapour lamp,

recovery took place In other words, the light from the lamp was the equivalent, therapeutically, of cod-liver oil This discovery was investigated by the Vienna commission and its truth confirmed

Now the light from a quartz mercury-vapour lamp possesses properties like those of the summer sun It seemed, therefore, that certain animal fats are related in some way, at least so far as their influence on the human body is concerned, to solar rays, whether natural or artificial Here, again, was a puzzle It was known that the chemical rays, that is the violet and ultra-violet rays, cannot penetrate the skin more than the fraction of a millimetre Could it be possible that rays which cannot pass through the thinnest skin could influence the body in much the same degree as fatty foods? Some extraordinary experiments were next carried out One of these was to keep a number of rats in the dark and without fat They developed rickets But, if the floor of the cage was spread with sawdust that had been exposed to sunlight rickets was prevented The conclusion is obvious Next, Professor Steenbock, of Wisconsin, discovered that many foods which did not contain animal fat could be charged with the fat-soluble vitamin by exposing them to the action of the summer sun or the quartz mercury-vapour lamp The vitamin in question was found to be different from the growth-promoting vitamin A and also from vitamins B and C So it was called vitamin D

Among substances widely distributed in nature, a constituent of all animal cells and of the natural oil of the human skin, is a solid alcohol known as cholesterol It soon developed that irradiated cholesterol, as commonly found, contained vitamin D, whereas cholesterol not so treated did not The rationale of the whole wonderful process is therefore this The cholesterol of the skin may be called the pro-vitamin The chemical rays do not shine through the skin, they shine on it, and, so doing, charge the cholesterol therein with vitamin D, which thus constitutes a store upon which the body may call at any time by means of the blood circulation However, pure cholesterol cannot store up vitamin D under the influence of light It has been found that the important substance is an impurity commonly

found in cholesterol, now known as "ergosterol" As has been aptly said, ergosterol is the true "sunlight sponge"

More recently, confirming this new principle, the Misses Hume and Smith, associated with Dr S N Lucas, have tried the effects of injections of irradiated cholesterol into the skin of rats and rabbits, and found that this procedure could prevent the development of rickets Thus, the mysterious action of sunlight is convincingly explained To the well-known physiological actions of the skin, as a protector, an organ of tactile sense, a heat regulator, and an eliminator, must be added another, fully as important, namely, that of absorbing and fixing the chemical rays of light, thus transforming them into a life-giving benefactor

Ergosterol is a white crystalline substance, first isolated from ergot of rye, by the French chemist Tauret When irradiated it becomes a pale yellowish oily substance of extraordinary potency A daily dose of one-hundred-millionth of a gram will produce normal calcification in a rat fed on a rickets-producing diet The manufacture of ergosterol is now an important industry, and it is possible to incorporate measured quantities of vitamin D with various foodstuffs, such as bread, biscuits, milk, butter, margarine, malt and chocolate The summer sun of Canada or Australia can now be trapped and confined in a bottle of milk or a pat of butter, and shipped to less favoured lands The whole thing reads like a fairy-tale

But, what are vitamins? Are they chemical entities or merely properties, hitherto unknown manifestations of electronic force, as tenuous as the fairies themselves? Only time can tell

It is a matter of common knowledge that diseases of the respiratory system, notably, influenza, pneumonia and bronchitis, are more frequent and more deadly during the winter months The general death rate, both in adults and children, is higher during the same period It is also known that from October until March the sun's light is very poor in the chemical rays We may safely say that the months of darkness are the months of disease and death In fact, we have to store up sufficient vitamins in summer to carry us over the winter

Dust, smoke (more abundant in winter), fog, confinement within doors, and heavy clothing are all factors that render less efficient the beneficent properties of the sun The remedies are obvious In passing, it may be remarked that, whatever may be thought of the clothing of the modern woman from the standpoint of art or morals, it at least is healthy Low-necked and sleeveless dresses, short skirts, and imitation-silk stockings certainly allow the ultra-violet rays fuller play than did the old-fashioned dress of heavy material, high-necked, long-sleeved and often trailing on the ground Could the modern man be induced to adopt a modified scout costume, with no hat, loose neck-cloth, and "shorts," he too would absorb more health One wonders if the Doukhobors in our North-west were not ahead of the times!

The cult of the sun is quickly coming to the fore The proof of this is seen in the remarkable results that are being obtained in the treatment of surgical tuberculosis by means of sun-baths, as in the Lord Mayor Teloea Hospitals at Alton in England, and at Leysin, Switzerland

But what is to be done in winter, when the sunlight is so ineffective Cod-liver oil, irradiated foodstuffs and ultra-violet-ray baths can meet the need to some extent Unfortunately, irradiating foodstuffs, to increase their store of vitamin D, often makes them unpalatable, and, what is perhaps worse, frequently destroys the other equally essential vitamins More study is needed here

The matter of the practical application of the principles so far discovered demands a word of caution that cannot be too frequently repeated In the case of sunlight, particularly when artificial, we are dealing with a potent agent Its value is beyond question We know very little about its harmful properties Yet, that it has some is equally beyond question Only continued research can put the question of sunlight therapy on a sane scientific basis Nations have been looking for their "place in the sun" So will individuals, but they should do it with circumspection and only under competent advice

In the meantime, we may expect to find, as has already so often been the case in religion and philosophy, that false prophets will arise, who will exploit the wonders of science and the credulity of the uninformed

for their own profit. Medical men must lend their influence to put a drag on the wheels of the coach of progress, when it takes this direction

A. G. NICHOLLS

ADMISSION TO MEDICAL PRACTICE

FROM sea to sea, across Canada, the medical schools have completed the work of another session, and at the convocation exercises of their several universities, some hundreds of young men and women have received the coveted diploma, the God-speed of Alma Mater and the plaudits of friends. They have left the university halls well instructed in the subjects of the medical curriculum, with the inspiration of earnest and efficient teachers, full of high hopes and lofty aspirations, anxious to take up the responsibilities of the physician's calling and to enter upon the great-enterprises of life.

But while they have satisfied university authorities that they are worthy of their diplomas and of the trust which the award of these diplomas implies, it is the belief of a very considerable proportion of the body politic that they have not been examined enough, and so they must now appear before other bodies of examiners with whom rests the decision as to whether or no they are to be permitted to practice their profession. Scarcely has the recent graduate recovered from the hectic days and nights of the final examination period, and scarcely have his ischial tuberosities ceased from burning under unwonted strain and friction, than he must begin preparation for another series of examinations which, though unlikely to be more searching, are very likely to be more trying, because conducted by men who are mostly complete strangers to the candidates and who may not be in very intimate touch with academic work.

The reason assigned for this duplication of examinations is that the public must be protected from doctors with inferior preparation. There was a time when inferior schools were numerous, though not in Canada. At the time of Confederation provision was made for provincial autonomy in educational matters, and in each province a body was constituted to administer a Medical Act. Each Medical Act was originally de-

signed for the protection of the public. Some have been so amended that they do not furnish adequate protection to the public, none are, or ever were, intended to be of special benefit to the medical profession.

Prior to, say, a quarter of a century ago, one of the chief duties of a provincial medical board was to prevent its province from being overrun with graduates of inferior schools which flourished in an adjoining country. The readiest method of elimination was the examination, and so each provincial board set up its own examination, which must be passed by everyone who wished the license to practise in that province.

Conditions have changed so entirely within the past few years that from all over Canada we hear voices raised in protest against present examination requirements. It is argued that Canada is no longer dependent in any degree upon other countries for her supply of physicians. Her own schools rank well amongst the medical schools of the world, and Canadian medical graduates rarely suffer by comparison with graduates of schools in other countries. The medical profession throughout Canada is fairly well organized, and is practically a unit in demanding high standards of medical education. Why, therefore, should not more responsibility be placed upon the universities and why should some measure not be devised which would place both tuition and the examinations under such control as would satisfy all concerned that graduation could be taken as evidence of professional capacity and trustworthiness? The retort which perhaps counts for most is that there will still be an occasional application for registration from a foreign school, and that difficulty might be experienced should a foreign candidate be required to take university rather than provincial examinations. The argument is offered for what it is worth. Possibly, it might be advisable to maintain intact the machinery for an occasional

provincial examination But cannot consideration now be given to some means which will obviate the necessity for graduates of Canadian medical schools to take other than the university examinations?

We look to the Motherland for our lead in many things In this particular, could not the procedure there, with such modifications as may be necessary, be made applicable to Canada? Thus the Medical Council of Canada might be empowered with general supervision of the curricula of the several schools and have valuers attend at examinations To graduates of all satis-

factory schools, the certificate of the Medical Council of Canada might be granted at once An unsatisfactory school would be quickly brought to the mark if its graduates were refused the certificate of the Council

There are difficulties in the way, of course, and the agreement of each province would have to be secured But these difficulties should be no greater than those encountered and overcome by Sir Thomas Roddick and those associated with him in getting the legislation known as the Canada Medical Act and in establishing the Medical Council of Canada

W H. HATTIE

CHRONIC APPENDICITIS

APPENDICITIS is a subject of ever-recurring interest, and, in view of its importance, will doubtless continue to be so The acute variety, usually clear-cut in its manifestations and onset, presents as a rule little difficulty in its recognition and treatment This is not the case with the chronic form In looking over recent articles and discussions on chronic appendicitis in the medical journals, one is struck with the haziness that invests the subject and the differences of opinion that very competent observers have expressed about it In fact, after perusing these, one is likely to fall into the same horrid state of incredulity that characterized Betsy Prig in regard to Mrs 'Arris, when she exclaimed "I don't believe there aint no sich person"

Assuming for the moment that there is such a condition as "chronic" appendicitis, the symptoms usually attributed to it are so inconstant and, moreover, may be produced by so many other conditions, that the clinician will frequently be in doubt Under such circumstances the pathologist has, or should have, the last word It may, then, very properly be asked what light he has to throw on the matter

At the outset it should be made clear that there is a common condition of involution, or "senility," of the appendix in which that structure becomes gradually atrophied and fibrosed, with obliteration of the lumen commencing at the tip This process begins in the early twenties, and affects about twenty-five per cent of appendices, according to Ribbert and A O J Kelly (Philadelphia

Medical Journal, 1899, IV, 928, 983 and 1032) Ribbert, in a study of four hundred appendices removed *post mortem*, found this process going on in the absence of any indications of previous inflammatory change Such appendices are smaller than normal, fibrous, but flaccid, and microscopical examination fails to reveal the presence of inflammatory cells or anything else, except involution, with a replacement fibrosis and a deposit of fat Some surgeons would include this condition with chronic appendicitis, but this classification is clearly wrong

Excluding such, then, instances are met with, both in operating-room and autopsy material, in which the appendix is large, thickened, rigid, somewhat hyaline in appearance, with more or less complete obliteration of the lumen, sometimes cystic It may also be adherent Microscopical examination shows diffuse infiltration of all the coats with inflammatory round cells and leucocytes, fibrosis, loss in parts of the mucosal lining, destruction of the lymphoid follicles, and obliteration of the cavity The process is entirely different from the other, and must be regarded as inflammatory

The question arises whether this latter condition is the result of previous acute attacks, to be called, perhaps, "relapsing" appendicitis, or whether it is "chronic", that is, slow and insidious from the start Inasmuch as appendices removed during an acute attack or in an interval sometimes show fibrotic changes, there can be no doubt that the first-mentioned possibility is a fact In this case, between the acute attacks there

a period of quiescence, but yet, the inflammatory process goes quietly on. It is stated, on good authority, that the appendix described above as that of chronic inflammation may be found in cases where a history of previous attacks of inflammation is lacking.

If so, this must be rare. It is to be regretted that some investigations should be made to clear up this point definitely.

While clinicians are disputing, there can be no doubt in the minds of the pathologists that there is such a condition as "chronic" appendicitis. It is undoubtedly, not often however. The main reason for this is that patients as a rule either are killed or die during the acute phase of the disease. Surgeons who admit the existence of chronic appendicitis seem to be agreed that the condition is rare.

The importance of this conclusion lies in the logical inference that, in the presence of symptoms suggestive of chronic appendicitis, to enter upon the great enterprise of appendectomy for this condition must not be diagnosed until everything else has been excluded.

A discussion on chronic appendicitis in children took place on February 24th, at a combined session of the sections of the Study of Disease in Children and of Surgery of the Royal Society of Medicine, in which some useful points were brought out. Mr A J Walton, in regard to incidence, reported 906 cases of appendicitis, 305 of which he regarded as chronic (33.66 per cent), 186 cases occurred in children under the age of fourteen years, of which 33 were chronic (17.74 per cent). That is to say, Mr Walton finds chronic appendicitis to be rather less than half as frequent in children under fourteen as in older persons. The figures are adults, 37.77 per cent, children, 17.74 per cent. None of his cases in children had been chronic from the beginning. His category of chronic cases included those without active symptoms, even though the condition was a late sequel of an acute attack, and also those with distension, fibrosis and stricture formation, and external dense adhesions. His list probably also included cases in which the appendix was not diseased, but showed senile atrophy or was involved in a Jackson's membrane. We have given reasons why senile atrophy should not be regarded as chronic appendicitis, and should like to know how many of Mr Walton's cases came

under this category. Evidently, the figure 33.66 per cent for chronic cases is remarkable. The number is too high. Of course, the figure does not apply to the juvenile cases, in which normal involution would not have been considered.

The conditions that should be considered in any given case before a diagnosis of chronic appendicitis is made are—acidosis, atony of the caecum with vaginal ptosis, ureteric calculus, "dyspepsia" due to peptic ulcer, gall-stones, tuberculosis and actinomycosis in the neighbourhood of the appendix, carcinoma of the appendix, and, in children, especially, acidosis, enlarged lymphnodes at the ileocaecal angle, mobile caecum, kinking of the ileum or appendix, inflammatory bands, intestinal colic, and, in girls, ovarian and other pelvic conditions. Acidosis has been mistaken for acute appendicitis, as pointed out by Drs Gibson and Mann in their paper published elsewhere in this issue, and may also be a cause of symptoms attributed to relapsing and chronic cases. This mistake is not likely to happen if the possibility is remembered and care exercised.

Pain in the right iliac fossa, especially if localized to McBurney's point, or coming on after exertion rather than after meals, would be suggestive of appendicitis. X-ray examination in some cases may be of service, though in others it may only confuse. If the appendix can be visualized after the barium meal, retains its load more than forty-eight hours, and is definitely restricted in movement on palpation, the presumption is fair that the appendix is involved in some way, though it need not be by chronic inflammation. Or, if the appendix does not fill, it would suggest kinking or obstruction of the lumen.

The importance of a correct diagnosis lies in the fact that only by having a correct and full idea of the condition present can the proper relief measures be instituted. It would be quite possible, for instance, to operate and remove an adherent appendix, where it was only secondarily involved, without relieving the symptoms, and even to make them worse by adding new adhesions to old. Clearly, much circumspection is needed in dealing with chronic appendicitis and the many conditions that may simulate it.

THE SIGNIFICANCE OF RÂLES

HOW much should we depend on râles as a guide in detecting the early stages of pulmonary disease? And once they are established how much are they an index as to the progress of the condition? These questions are raised by Dr F H Heise (*Am Res of Tuberc*, April, 1928, vii), in a study of a series of tuberculous patients at the Trudeau Sanatorium, and his answer tends to the general conclusion that râles are by no means reliable guides in early diagnosis, nor yet in prognosis. He has examined case records of 1877 tuberculous patients, and has compared the findings recorded on their admission with the confirmed diagnosis made later on, making a special point of the degree of inflammation given by the x-ray. Dividing his cases into groups of minimal, moderately advanced, and far advanced, his investigations bring out the following points:

In 351 of the minimal cases only 145, or 41 per cent, were found to have definite or even questionable râles on the first examination, leaving more than half (59 per cent) with no râles discovered at this stage. In nearly all of these minimal cases, however, definite x-ray changes were found.

The moderately advanced cases formed a group of 1,299, and of these it was found that 980, or 75 per cent, showed râles, leaving a rather large percentage (considering the degree of the disease) in which diagnosis would not have been made if râles alone had been the guide.

In the far advanced cases, as might be expected, râles were noted in nearly 90 per cent of 227 patients.

It is difficult to lay down hard and fast principles regarding the significance of râles. There is probably no other physical sign to which the medical man is introduced so early, and none other which we must more clearly learn to recognize, and also to discount, at its proper value. It is not to be expected that it will be disregarded as a guide in diagnosis, but with such discrepancies between their existence (or detection) and the proved presence of early disease, there should be less temptation to wait for their appearance before deciding that disease is developing. After all, their detection is affected by

anatomical considerations, and, besides, the earliest stages of tuberculosis may not necessarily be accompanied by râles. There is still room for proof as to how the finer type of râles are produced.

What we should learn from this investigation, therefore, is not to underestimate the significance of râles *per se*, but rather to refuse to be misled into a feeling of security because we cannot detect them.

The next point taken up by Dr Heise deals with the information that râles give in regard to the cause of the disease. Are we to assume that the improvement in a focus is accompanied by a corresponding diminution in the number of râles and the size of the area over which they are heard, or *vice versa*? There is no doubt that in acute relapses or well marked improvements changes in the quality and number of râles can be easily appreciated, but do these changes coincide enough to give the fullest information as to the progress of the disease?

To answer this question, 412 records were gone over to see how changes in the râles compared with what the x-ray showed, and it was found that during a period of six months the râles remained the same as to area and character in 111 cases. But the x-ray examination of these cases showed definite improvement in 93 per cent, relapse in 2 per cent, and a stationary condition in only 5 per cent. From this it may be assumed that, if râles are to be taken as an index of progress, their being stationary is strongly in favour of improvement in the lesion.

Even when the râles were found to have increased in area, however, x-ray showed that in a large percentage there was improvement, and that only a small number had remained stationary. In only 23 per cent did the increase in râles coincide with an advance as shown by the x-ray. It was when the râles were in process of diminishing that there was most nearly complete correspondence in 88 per cent of this type of patient the improvement was confirmed by the x-ray. In a small percentage, however, there was relapse or a stationary condition. Under these conditions, it seems fairly safe to conclude that lessening of the number and

become a great beneficent movement which has extended into every civilized country

Henri Dunant was the son of Jean-Jacques Dunant, a member of the Council of Geneva, and of Anne-Antoinette Colladon, the sister of a famous Swiss surgeon. He was brought up in an atmosphere of refinement, religion, and philanthropy, and early took an interest in certain movements for the betterment of the lot of mankind which were being talked about at that time. Besides his mother, three women in particular seem to have influenced his mind, Harriet Beecher Stowe, whom he met in Geneva in 1853, Elizabeth Fry, and Florence Nightingale. The questions of slavery, prison reform, and military nursing, then, interested him greatly.

His opportunity came in 1859 when, travelling as a tourist, he arrived at the field of Solferino as the great battle was going on between the French and Italians on the one side and the Austrians on the other. Three hundred thousand men were engaged in the struggle for fifteen hours. The Austrians were routed, and from thirty to forty thousand men left, dead, dying, and injured, on the field, without anyone to come to their aid. Shocked at the sight, Dunant organized a band of volunteer workers, who for several days worked incessantly to relieve the situation. The neighbouring town of Castiglione became one vast hospital. The authorities issued an edict of neutrality to protect the workers, and they were officially recognized by the peasant costume of Lombardy which they wore.

This experience determined his future activities. For the next two or three years he travelled over Europe, lecturing and writing about the crying need for the organization of a proper medical and nursing service for times of war. Then, in 1862, he published his book *Un Souvenir de Solferino*, which attracted much attention. In it he drew a graphic picture of the terrible aftermath of the battle, the unbelievable suffering, and the heroic efforts made to meet the situation. He asked this question, "Why have we thought it well to recall these scenes of grief and desolation, to recount such lamentable and gruesome details, to draw such vivid pictures of despair?" The answer he gave is in the form of another question: "Would it not be possible to found and organize in all civilized countries permanent societies of volunteers which in time of war would render succour to the wounded without distinction of nationality?"

Another lecture tour followed, and Dunant's ideas gained acceptance more and more. The Society of Public Safety of Geneva, under its president, M. Gustave Moynier, took up the matter and organized the first Geneva Conference in 1863. Dunant's views were accepted, the scheme was systematized, and nation after nation adopted the provisions of the Treaty of

Geneva, until to-day fifty-nine nations of the world have subscribed to its articles. The inspiration of a simple citizen has become an international law among civilized peoples.

But Dunant's subsequent fate was only just saved from being a tragedy. He had spent his substance for the good of mankind, in the enthusiasm which attended the great movement he had initiated; his part was overlooked, and he became an inmate of an almshouse. Fortunately, his plight was discovered by a French journalist, and the world was quick to rectify its neglect. Dunant was awarded, jointly with Frederic Passy, the Nobel Peace Prize in 1901. This honour was well bestowed, for by this time, in Dunant's mind the great idea of the Red Cross movement had expanded into another, greater still one that will in time make the Red Cross less necessary—the idea that war must be outlawed among civilized races. In this way he continued to labour, and in 1910 died full of years and honour.

A. G. NICHOLLS

HIDEYO NOGUCHI

Dr Hideyo Noguchi, of the Rockefeller Institute, died May 21st on the Gold Coast from yellow fever, while completing his studies on this disease. Thus, one more name is added to the list of medical men who have died as martyrs of science, in the search for truth. We are reminded of Lazear, Yeissin, Dutton, Ricketts, McClintick, Pirie, and Adrian Stokes, to name only some.

Noguchi was born in Japan in 1876. Coming to America, he became Assistant in Pathology in 1901 at the University of Pennsylvania, in 1903, Research Assistant in the Carnegie Institution, in 1914, a member of the Rockefeller Institute for Medical Research.

His contributions to medical science were numerous and of the first order. Among them were, the artificial cultivation of *spirochaeta pallidum*, the demonstration of the organism of syphilis in the brain in general paralysis, and in the spinal cord in locomotor ataxia, the introduction of the luetin test for syphilis, the cultivation of micro-organisms associated with infantile paralysis and rabies, a method for attaining a bacteria-free vaccine for small-pox, and the isolation and cultivation of *Leptospira icteroides*, and the development of a preventive vaccine and serum in connection with yellow fever.

He was the recipient of honours too numerous to mention here. His death removes one of the outstanding figures in our profession, and leaves the world of science much poorer.

PEACE-TIME POLICY AND HEALTH PROGRAM OF THE RED CROSS IN CANADA*

A REVELATION OF THE WAR

By JAMES W. ROBERTSON, C. M. G., LL. D.

Chairman of Council, Canadian Red Cross Society
Ottawa

For the first time in all history the Great War furnished the occasion and made evident the necessity for a medical examination of practically the entire manhood between certain ages, of Great Britain and some other countries. That is a very noteworthy fact. The results shown by these examinations were not published during the War.

The Report, known as Volume 1, upon the physical examination of men of military age by National Service Medical Boards in Great Britain from November 1, 1917 to October 31, 1918, covers practically the last year of the war. The number of examinations held during that period was 2,425,181, and a summary of the results shows the following facts:

Of every nine men of military age in Great Britain, on the average three were perfectly fit and healthy.

Two were upon a definitely infirm plane of health and strength.

Three were incapable of undergoing more than a moderate degree of physical exertion and could almost (in view of their age) be described with justice as physical wrecks.

The remaining one was a chronic invalid with a precarious hold on life.

After reviewing the whole situation in the light of previous volunteer enlistments, etc., the report goes on to say:

"It seems probable, therefore, that the men examined in the year under review, may be regarded in the aggregate as fairly representing the manhood of military age of the country in the early part of the twentieth century from the standpoint of health and physique, and that deductions founded upon the observations made at the medical examination of these men may be legitimately looked upon as a trustworthy criterion of the national health of the period."

ACTION TO MEET THE SITUATION

What about the women and children in a nation whose men at military age were in that state? Disaster from without had been vanquished, but danger threatened from within.

*This being the centenary of the birth of Henri Dunant, the founder of the Red Cross Society, general attention has been again directed very strongly to this organization. At the request of the *Journal* Dr. Robertson, Chairman of the Council of the Canadian Red Cross Society, has been good enough to prepare this statement on the activities of the Red Cross in Canada. We desire to thank him cordially for this contribution which is both instructive and timely.

Steps were therefore taken immediately (December, 1918) at the close of the war by the "Big Five," as they were called—Britain, France, Italy, Japan, the United States—to consider and deal with this situation that faced them all. A conference of the medical experts from these five nations took place at Cannes in the south of France in April, 1919. A minute adopted by the Conference referred to the world-wide prevalence of disease and suffering as "due to widespread ignorance and lack of application of well-established facts and methods capable either of largely restricting disease or of preventing it altogether." The danger and the damage were due to ignorance and lack of application on the part of the people, not to want of knowledge and skill on the part of leaders.

Subsequently, because of the conclusions of these medical experts, the Peace Conference itself put into the *Covenant of the League of Nations*, Article XXV, in which the members of the League pledged themselves "to encourage and promote the establishment and co-operation of duly authorized voluntary national Red Cross organizations having as purposes the improvement of health the prevention of disease and the mitigation of suffering throughout the world."

The Parliament of Canada proceeded to alter the constitution of the Red Cross Society, to give it the necessary authority "in time of peace or war to carry on and assist in work for the improvement of health, the prevention of disease and the mitigation of suffering throughout the world."

That is the mandate to the Society to go ahead with its peace-time program. The great need of the present time is the improvement of personal and home hygiene. Manifestly, that can be secured only by the willing and intelligent participation of individual men and women and boys and girls. The thing to be done is to bridge the gap between the knowledge of the essentials of personal hygiene and home hygiene now possessed by the natural leaders in preventive and protective medicine—namely, the doctors, public health officials and nurses—and the knowledge and practice generally of the women who are in charge of homes and schools.

RESULTS FROM THE EXAMINATION OF CHILDREN

Take one outstanding and typical example of the situation in Canada calling for action. At the end of the war, the Patriotic Fund, in Montreal, caused an examination to be made of a thousand children—children who were well, not sick, and whose mothers were getting some help from the Patriotic Fund because their fathers had been overseas. A great many more than a thousand were examined, and, as a result of the examination of the first thousand children, a great many de-

fects were revealed. The list shows an astonishing number of defects among these supposedly healthy children of the soldiers. Altogether, 6,404 defects were found. 694 children had "bad" teeth and gums, 918 of these 1,000 children were tea or coffee drinkers. The number of undernourished children recorded in that group of 1,000 was 299, about thirty per cent.

WORLD-WIDE MOVEMENT FOR HEALTH AND AND WELL-BEING

A Red Cross peace-time policy and program of work is now being carried on in fifty-four countries. It is, perhaps, the greatest world-wide movement on behalf of the well-being of women and children and the welfare of people in general since the introduction of Christianity. There has been nothing in the same class with it, nothing comparable to it in scope and fundamental values and nothing with similar promise of the early realization of its highest aims, as indicated by its marvellous achievements during the seven brief years it has been in operation.

The Junior Red Cross has already (by the end of 1927) been organized in 5,744 classrooms in Canada, with a membership of 157,155 children, banded together to carry out in practice the rules of healthy living and thereby form good health habits. The Junior Red Cross Movement is going on in thirty-four different countries with a membership of over ten millions of children.

HEALTH AND GOOD CITIZENSHIP FOR JUNIORS

The main object of the Junior Red Cross in connection with the schools is to help to bring about correction of the conditions indicated, as far as possible and, chiefly, by the children's own desire to participate. Every Department of Education has sanctioned the activities of the Junior Red Cross in the schools, and some Ministers of Education have gone so far as to press upon the teachers the desirability of giving it the quickest and widest application. The primary purpose of the Junior Red Cross is to get the boys and girls interested in learning and doing voluntarily those things which promote health knowledge and health habits, linking up a knowledge of hygiene with habits of living so that the child may have them for all time. The foundation of national fitness and national efficiency lies primarily in the establishment of health habits, and this can only be thoroughly done through the willing concurrence of the person concerned.

Unquestionably, the physical vigor of this nation could be greatly improved in two generations if, by iteration and reiteration, precept, example, and experience, we could so train our children that they would voluntarily and by force of habit keep their mouths clean, drink milk, eat wholesome cereals, consume fresh vegetables and fresh fruit, drink plenty of water, play in the open air, sleep 10 to 12 hours, and follow all the other laws of health that are at the back of the activities of the Junior Red Cross.

THE CRIPPLED CHILDREN'S FUND

In promoting the idea of helpfulness to others, the Junior Red Cross in Canada is chiefly concerned with the Crippled Children's Fund. In this connection a very wide interpretation is given to the word "crippled." Out of money provided by the children themselves, through a membership fee of twenty-five cents a year, or their other contributions to the Crippled Children's Fund, it pays railway fare to hospital and hospital expenses of crippled children whose parents are unable to do it for them. The Junior Red Cross Fund has taken care of more than 5,000 handicapped children up to the end of 1927. That is abundantly worth while. That is service, not in the vague and the abstract, but in a very real sense. It is altruism in action, goodwill in action, not in passive contemplation. In practical reality the children are acquiring good health habits, the essentials of good citizenship, of altruism and of international friendliness.

The net expenditure for the Junior Red Cross, last year, amounted to \$77,807 00.

OUTPOST HOSPITALS AND NURSING STATIONS

In its forty Outpost Hospitals and Nursing Stations, the Red Cross furnishes skilled professional service to the pioneers on the frontiers of settlement in six provinces. Last year more than 12,000 persons were treated in and through them. 866 were confinement cases, most of whom otherwise would have been without competent care. If funds permitted, many more Outposts might be established, to the incalculable advantage of pioneer settlers. The Outposts are always established and maintained in co-operation with the people of the locality and the Provincial Departments of Health. The net expenditure for this service last year amounted to \$139,866 00.

The type of Outpost selected for any community depends, of course, on the peculiar needs of the community and the resources available. There are, however, three types.

(1) The centre for field nursing. The nurse works in the homes and schools of the district, but no provision is made for in-patients.

(2) The rural outpost, with accommodation for one or two bed-patients, but with field-nursing as the chief work of the nurse.

(3) The outpost in a village or small town which functions as a small hospital.

SEAPORT NURSERIES

Canada spends large sums in bringing immigrants to its eastern seaports, and the Red Cross realized that it might contribute something to the work. Consequently, in co-operation with the Department of Immigration and the Health Department, "Seaport Nurseries" were established in Halifax, Saint John and Quebec. In these are welcomed, under an emblem that wins their immediate recognition, the mothers and children who have come to find new homes in a

new land. The youngsters are fed and cared for, the mothers are given a comforting and kindly atmosphere in which to refresh themselves after their ocean voyage. Advice is often asked and as often cheerfully provided, and, when the time comes, the new citizens undertake the next stage of their journey happy in the knowledge that their welfare is a matter of concern to the Society that knows no national boundaries. They have learned, too, that on their arrival at their destinations other Red Cross workers stand ready to furnish any further service that may be found to be necessary. During the last year 35,312 infants, children and women were cared for and follow-up cards were sent for 5,219 families. The cost of these nurseries, last year, amounted to slightly over \$12,000.00.

HOME NURSING CLASSES

A course of instruction in Home Nursing and Home Hygiene was established by the Red Cross in 1924. 1,004 classes have been organized up to the end of 1927 and the course taken by over 13,000 women. These women have gained a knowledge of food-values and the importance of a well-balanced dietary to good health. They have been given simple instruction in the recognition of illness, and have learned the elementary principles of the care of the sick. They have thus become better managers of their own households, and they have been able to instruct and advise their less well-informed neighbours.

RELIEF SERVICE IN DISASTERS

Always in readiness, the Red Cross furnishes Disaster Relief to any community overwhelmed by catastrophe. Its services have been needed in the Haileybury conflagration, the Cochrane epidemic, a cyclone on the Prairies, and, only last year, when two villages in Quebec were destroyed by fire. If the whole world is stirred by an immense calamity, the Red Cross forms a world-wide agency for the collection and distribution of money and supplies.

SERVING DISABLED EX-SERVICE MEN

Red Cross service is still needed for some of those disabled in the war. Its function has been to supplement official services and to meet the needs of those cases which do not fall within government regulations. Red Cross visitors prove to the several thousands of those still in hospitals that they have not been forgotten. Last year this service required an expenditure of \$145,576.00.

POPULAR PUBLICATIONS

The Red Cross publishes and distributes authentic and appropriate health literature in a form that is easily understood by everybody. It employs most expert assistance and acts as interpreter between the scientist and the public, to the

end that the every-day citizen may have the best information and instruction obtainable. It publishes two magazines with a joint circulation of about 60,000 copies a month.

HEALTH OPINIONS AND HEALTH CONSCIENCES

In striving to carry out the purposes assigned to it under the Peace Treaty, the Red Cross has sought to translate them into practical health services such as I have indicated. It seeks to co-operate with other organizations, official and voluntary, and to strengthen all good health measures. It lays particular emphasis upon the necessity of seeking and accepting the advice and guidance of the natural and competent leaders in all health matters, namely, the doctors, public health officials, public health nurses and other competent teachers. Only by following such well trained leaders—men and women of high intelligence, professional ability, irreproachable integrity and devotion to the public good—can safe and continuing progress be made. The rôle of the Red Cross is to back up their services, to create public opinion in support of their work, and to diffuse such popular information among laymen and laywomen as will make opportunities for the special professional knowledge of the few to become beneficially effective in the lives of all.

REPORT OF THE SCHOOL OF PUBLIC HEALTH NURSING OF THE UNIVERSITY OF MONTREAL AND THE FRENCH HEALTH CENTRE FOR 1927

By J. A. BAUDOUIN, M.D., *Director*

Montreal

We have in 1927 completed the second year of our activities. The area covered in the work of our Health Centre, *viz.*, the parishes of St. Catherine and the Sacred Heart, comprises a population of about 19,000 souls. A total of 23,292 visits were made to the homes in this district, or an average of 1,941 per month. This represents an increase of 1,241 visits over the year 1926. These visits were made to 4,658 cases, an increase of 1,719 above those of 1926. The total attendances at the various clinics for the year amounted to 10,357, an increase of 3,047 over the previous year.

To accomplish the work there were available a personnel composed of one Directress of Nurses, two assistants, four staff nurses (the contribution of the Montreal Anti-tuberculosis and General Health League), and an average of 10 pupil nurses (for a portion of their time).

The various activities of our organizations may be classified under the following general headings: Child Hygiene, School Hygiene,

Industrial Hygiene, Home Care of the Sick, and Contagious Disease Service

CHILD HYGIENE

The Department of Child Hygiene comprises the following services: Pre-natal Care, Post-Partum Care, Care of the Newborn, Care of the Well Baby, and Children of Pre-School Age.

The Pre-Natal Service has as its objective the decrease in maternal mortality, as well as the decrease in deaths of infants attributable to congenital debility.

The total number of mothers under supervision was 407. The total number of births in the area was 656. Therefore, 62 per cent of the births were, as it were, supervised pre-natally. If we recall that an enrolment of 25 per cent is regarded as satisfactory, ours approaches the ideal. Forty-three per cent of the total enrolment occurred during the first four months, a very satisfying fact. Besides the visits made in these cases, the School maintains a Pre-Natal Consultation Clinic, which was attended by 134 expectant mothers. Furthermore, about 53 per cent of the expectant mothers have, on the advice of the nurses, consulted a family physician.

All this work has shown its results, in that only two deaths occurred from puerperal causes.

Post-Partum Service—About 65 per cent of the new mothers were visited by nurses, who render service in conformity with the directions given by the family physician.

Care of the Newborn—The nurses' visits are made daily for the first week, then once a week, and cover the whole of the first month. This service is most valuable in its contribution to the campaign against the too numerous deaths that occur shortly after birth.

Care of the Well Baby—Infants aged from one month to two years come under this service. One visit is made to each child per month. Moreover, the mothers are urged to bring their babies to the consultation clinics specially provided for them. All these activities have given us results that we consider very encouraging. In the case of St. Catherine's parish, the following table will establish this—

INFANT MORTALITY

Year	Births	Deaths from 0 to 1 year	Rate of Infant Mortality
1915	334	94	281
1916	310	94	303
1917	298	82	275
1918	327	86	263
1919	308	76	247
1920	324	72	222
1921	300	47	156
1922	264	39	148
1923	274	56	204
1924	273	60	220
1925	265	34	128
1926	240	37	154
1927	265	23	87

The year 1927 has been the best that St. Catherine's parish has ever had. It shows at the same time an increase in the number of births and a decrease in the deaths, which is the most convincing demonstration that it is possible to furnish.

Gastro-enteritis and congenital debility are still the chief causes of infantile deaths. To combat the former we insist on breast-feeding. The importance of this is shown by the fact that this year all the deaths from intestinal trouble occurred in babies who were bottle-fed. Congenital debility depends mostly on prematurity. Here, the medical supervision of the expectant mother is of the greatest importance.

Service for Children of Pre-School Age—This deals with children between the ages of two and seven years. Many of these are subject to malnutrition, physical defects, and contagious diseases. Two hundred and forty of these children attended the appropriate clinics.

CONTAGIOUS DISEASE SERVICE

Since the visit to the University of Professor A. Pettit, the School has been the distributing centre for the vaccine known as BCG. Three hundred and twenty-one vaccinations were performed, and of these 39 were revaccinated at the end of the year. Four deaths occurred, but none were due to tuberculosis. Fifteen of our immunized babies have been in contact with cases of active tuberculosis. Of these, thirteen are in good health, one is dead from capillary bronchitis, the other is sick. In the last case, there is a cough, and the doctor states that one lung is diseased.

Our tuberculosis service comprises also the home-visitation of the sick in our district. Seventy-five cases of tuberculosis are under our constant supervision. This number constitutes about one-third of the estimated cases in the district. The great majority of our cases are recruited from school children, those who have finished school, and adults from twenty-five to forty-five years of age.

In the families of our patients 339 contacts were found who live under the constant threat of infection. One hundred and forty-five of these have been examined medically. Fifty-two are in good health, 72 are suffering from malnutrition, and 21 are actually under supervision. Twelve children, threatened with tuberculosis, have been admitted to the Camp David of the Bruchesi Institute, and have benefited greatly by their stay in the country.

In the case of diphtheria, as this is a disease that is specially dangerous to children of pre-school age it is upon them that our attention has been focussed. With anatoxin-Ramon it is possible to confer a permanent immunity against this disease. A first injection of anatoxin was given to 236 children, 203 of these

came back for their second injection, and 15% of the latter came back for their third. The parents are asked to bring back their children four months after the last injection, in order that we may determine their immunity by means of the Schick test. More than 108 have been immunized, though only that number of certificates has been issued by the doctor in charge. Our figures show that only 28 per cent of the children of pre-school age in the parish of St. Catherine can be regarded as immunized, and 5 per cent in that of the Sacred Heart.

In dealing with other contagious diseases we are, of course, not so well armed. We have recourse to notification, isolation, the removal of contacts from school, and disinfection. To obtain necessary experience, our pupil nurses accompany the municipal nurse on her official visits. The experience that our nurses get is quite extensive, and I take this opportunity of thanking Dr. Boucher and the members of his staff for the facilities provided.

SCHOOL HYGIENE

The activities carried on for the benefit of school children include medical inspection service and a psychiatric clinic.

By agreement with the city Health Department the School furnishes visiting nurses to two schools (Salaberry and Garneau), which have an attendance of 1,182 children. In the course of their visits the nurses give talks on various health topics. Visits are, also, made to the homes of the children, to determine causes of absence, and to follow up cases of physical defect that have been noted. During these visits the nurses educate the parents and endeavour to obtain their co-operation in having the necessary treatments carried out.

Forty-six children were submitted to a psychiatric examination. Of this number 29 were found to be normal, and 17 showed some degree of retardation in their mental development. In three of the cases the retardation was of three years or more. This raises the question of the provision of a special class for those defective mentally. In connection with this general subject, we are glad to state that we have concluded a most fortunate arrangement with the National Committee for Mental Hygiene. Thanks to the generous co-operation of this Committee, Dr. J. A. Lussier was enabled to make some very valuable observations in the schools of Toronto, which are noted in his annual report. Furthermore, Mlle. Blanche Bourbonnais, a graduate of our school, was asked by the same committee to spend two months in Toronto, which has enabled her to render us very valuable service.

HOME CARE OF THE SICK

The care of the sick in their homes consti-

tutes a necessary part in a course designed for nurses taking up public health work. The service which a nurse is thus called upon to render in a family is always appreciated, and constitutes one of the best means of introduction into such families, of gaining their co-operation, and of making progress in health matters.

INDUSTRIAL HYGIENE

To meet the needs of the time the program of the School of Public Health Nursing includes Industrial Hygiene. We have an understanding with the Imperial Tobacco Company, the Simons Tobacco Company, the American Can Company, the Davies Meat Canning Company, the Dominion and Columbus Rubber Companies, whereby our students are permitted to spend some days in these establishments. To the representatives of these companies we desire to express our gratitude.

In concluding this report on the activities of the School of Public Health Nursing and of the Demonstration Centre, I must, in all justice, give credit for our success to the devoted and competent staff that we are fortunate enough to possess. Nor would the work accomplished been possible without the invaluable aid that we have received from the Government through the Hon. Athanase David, Provincial Secretary, from the City of Montreal, from the Montreal Anti-tuberculosis and General Health League, and from the Metropolitan Life Insurance Company. To these generous benefactors, I desire, in the name of all my colleagues, to express our sincere and deep gratitude.

CONCLUSIONS

1 The lowering of the infant mortality rate is the first indication of the success obtained by a health organization. A campaign against those factors that are most important in causing death is that most likely to be followed by practical beneficial results, and is, also, the most economical.

2 The administration of the vaccine B.C.G. is easy, and ought to be made general throughout the province as soon as possible, in order to enhance the results of the campaign against tuberculosis.

3 Immunization against diphtheria constitutes our chief weapon in the campaign against this disease. Extended to all children of pre-school age, this proceeding is capable of extinguishing this disease, thereby preserving to us the lives of the 400 children that are lost to the province every year.

4 The contribution of Mental Hygiene to the great cause of teaching is eminently valuable and should become still more so in the course of time.

(An abridgement of the report kindly furnished by Dr. Baudouin, who deserves congratulations on the good work accomplished—Ed.)

GASTRO-ŒSOPHAGEAL CARCINOMA ITS DIAGNOSIS*

By LOUIS J. NOTKIN, M.D.

Montreal

Early diagnosis of malignant lesions of the cardia and fundus frequently offers great difficulties. The relatively benign nature of carcinoma in these situations makes it imperative that diagnosis be made early, if surgery is to be of value.

Carcinoma of the fundus and of the cardia is of relatively frequent occurrence. The incidence reported by different observers varies from 7 to 20 per cent of all cancers of the stomach. Other observers note that 40 to 50 per cent of all cases of cancer of the œsophagus have their origin at the cardia. The difficulty in diagnosis lies in the absence of a clear-cut group of symptoms characteristic of the disease, and is increased by the limitations of the various methods of diagnostic technique. The symptoms of cancer involving the fundus are very often referred to the œsophagus, while symptoms of cancer of the cardia are generally gastric in nature. In the former case incomplete examination not infrequently results in the diagnosis of cardio-spasm or spasm of the œsophagus. In the latter case, where the symptoms suggest a gastric origin, x-ray examination may reveal an irregularity of the duodenal cap, which in this case is only an expression of the increased irritability of the stomach. In this manner only the associated condition is disclosed and the disease overlooked. In the presence of œsophageal symptoms the possibility of gastric carcinoma must always be borne in mind.

The onset of gastric carcinoma is sudden in a large proportion of cases, and gradual in a smaller number, where the cancer develops from a pre-existing ulcer. In all cases, however, there is a symptomless latent period of several months' duration and the initial stage at which the patient becomes aware of the disturbance may be regarded as the second stage of the disease. Loss of appetite, pain, gas eructations, regurgitation of small quantities of food or sour liquid, rapid satiation, and dysphagia are the symptoms most frequently complained of. Of these, dysphagia only, with or without remissions, is suggestive of lesions of the œsophagus, cardia or fundus. Malnutrition, cachexia, fever and enlarged cervical glands are late manifestations and are frequently absent.

The test meal gives no conclusive evidence, while estimation of the acidity may often prove misleading rather than helpful. Secondary anæmia, if it occurs at all, is a late sign. Occult blood in the stools is an almost constant and early finding. Occasionally, occult blood may be

temporarily absent, hence the importance of repeated examination. Tarry stools are much less frequent.

While certain of the above signs and symptoms are suggestive, no one, or any group, offers proof positive of the presence of the malignant disease in the areas under discussion. The x-ray must be depended upon for the conclusive evidence. Œsophagoscopy is of little or no value in the diagnosis of cancer of the cardia or fundus, even in the presence of extensive invasion.

X-RAY DIAGNOSIS

From the roentgenological point of view there are two pathological groups of fundal and cardiac cancer—(1) infiltrating flat growths, associated with shrinking (scirrhus type), and (2) the fungating, cauliflower-type of growth. The medullary type of tumour, which in the rest of the stomach gives rise to a filling defect, is seen in the fundus as a tumour-shadow, jutting into the gas bubble which may divide the barium stream as it enters the stomach. This form of tumour growth causes comparatively little difficulty in diagnosis. It is the flat, squamous-celled type that is troublesome. For the diagnosis of cancer at the cardia we must depend upon irregularity of the cardia and of the terminal portion of the œsophagus as direct signs.

The main difficulties in the x-ray diagnosis of cancer of the fundus and cardia are those caused by the location of the growth. In the case of carcinoma situated at the fundus the lesion may be overlooked, unless it is the medullary form and encroaches upon the gas-bubble, because the barium suspension does not fill the fundus in the upright position, nor do peristaltic waves ordinarily traverse the upper pole of the stomach. In the ordinary, routine positions of examination, cancer of the cardia may be overlooked, because the liver-shadow hides the subdiaphragmatic portion of the œsophagus, and, in the horizontal position, because the last portion of the œsophagus and with it the cardia are covered by the filled fundus. Carcinoma of the fundus, as has been previously stated, is frequently associated with spasm of the cardia or lower œsophagus, and that of the cardia with spasm of the lower œsophagus. These associated spastic manifestations may mask the more serious condition lower down in the gastrointestinal tract. It is necessary, therefore, when ordinary methods fail, to resort to special methods of x-ray examination in suspected cases.

If the barium suspension enters the stomach without being arrested in its downward course, or without disclosing some irregularity of the areas under inspection, the barium paste should be tried. Very careful screen examination, in addition to skiagraphy, is essential. The patient is examined in the upright left oblique position, to begin with. This position brings into view the œsophagus in the greater part of its course. The swallowed barium is followed in its passage through the œsophagus, particular attention

* The complete paper, including bibliography and x-ray plates, appeared in *Surg., Gynec., & Obst.*, May, 1928.

From the Gastro Intestinal Clinic, Department of Medicine, Royal Victoria Hospital, Montreal.

being paid to the manner of its entry into the stomach. There is frequently partial or complete arrest of the barium at the cardia, and, in the case of fungating tumours of the lesser curvature near the cardia a tortuosity of the barium stream, or a tumour-shadow silhouetted against the background of the gas bubble may be disclosed. When complete arrest of the barium occurs at the lower end of the œsophagus, in spite of taking small quantities at a time, spasm of the cardia or of the œsophagus is diagnosed. Absence of marked dilatation or tortuosity of the œsophagus will tend to rule out true cardio-spasm as opposed to spasm of the œsophagus. Smoothness of the contours of the lower end of the barium-filled œsophagus does not rule out malignancy, since spasm occurring on the oral side of a lesion may be situated in an entirely normal portion of the œsophagus. In idiopathic dilatation the subdiaphragmatic segment of the œsophagus often lies transversely and is directed to the left, while in carcinoma it follows in almost vertical direction, and there does not occur any greater lateral deviation to the left than that usually present. The triangular space, formed where the œsophagus turns forward and to the left to enter the diaphragm, is often obliterated in malignancy.

If, in spite of slow sipping, the barium does not enter the stomach, and the œsophagus is not found to be markedly dilated or tortuous, that is, if signs of longstanding obstruction are absent, the patient should be re-examined after the administration of antispasmodics to the limit of tolerance.

Shrinking of the stomach, and its displacement upward and to the left, may be present in scirrhus carcinoma of the stomach. Diminution in the size of the stomach in cancer of the cardia also occurs. Both signs were present in one of the cases reported here.

Absence of the gas-bubble is an important sign. Infiltration of the cardia may give rise to inefficiency of the cardiac sphincter, resulting in escape of the gas normally filling the fundus. Thus, a permanently absent gas bubble is evidence of patency of the cardia and points to the possible presence of infiltration.

The patient should next be examined in the horizontal position. For proper examination of the fundus it is necessary to have the stomach well filled. Normally, the fundus fills the dome of the left diaphragm and lies in close apposition to it. Its upper limit traces a smooth wide arc. Occasionally, this contour is dentate, this appearance probably having the same significance as the dentate appearance of the greater curvature due to contracting of the muscularis mucosæ. This irregularity must not be confused with that produced by a local lesion. In the latter case the irregularity is not regularly dentate and does not follow the sweeping arch of the fundus, the transverse diameter of the fundus is also much narrower than is usual, due to encroachment of

the tumour upon the lumen of the stomach, or to shrinkage in scirrhus forms.

If cardinal examination, as outlined above, fails to reveal the presence of a lesion, the region of the cardia should then be thoroughly examined. The cardia is not brought into view for careful inspection by ordinary methods of examination. The reasons for this have already been mentioned. O. Ridder advocates the Stuertz position. The stomach is filled with gas and the patient fluoroscoped in an oblique position, the rays being directed from the right, posteriorly and above, to the left anteriorly and below. An unobstructed view of the cardia and terminal œsophagus is obtained in this manner. According to Puliguay, carcinoma of the cardia can be recognized even in cases showing but little change in the stomach wall, but in which the normal cardinal mechanism is disturbed. There is a persistent tracking of barium through the cardia, and as a rule, the outlines of the opaque meal as it passes through the cardia, are seen to be irregular and ragged. It is only, however, the irregularity of the contrast silhouette in the region of the cardia, with the patient in the Trendelenburg position that can be considered as direct x-ray evidence. In cancer of the cardia the upper pole of the stomach is frequently an unusually great distance away from the diaphragm.

The direct signs of gastro-œsophageal cancer are—

- 1 A tumour shadow bulging into the gas-bubble
- 2 Irregularity of the barium contour as it passes through the cardia
- 3 Splitting of the barium stream on entering stomach

The indirect signs are—

- 1 Spasm of the œsophagus or cardia
- 2 Disturbance of the cardiac mechanism
- 3 Absence of the gas-bubble
- 4 Shrinking of the stomach
- 5 Drawing of the stomach upward and to the left
- 6 Increased distance between the upper pole of the stomach and the diaphragm
- 7 Narrowing of the fundus
- 8 Obliteration of the triangular space mentioned above

CASE I

I. H., male, aged 40 years, was first seen on May 18, 1925. He complained of difficulty in swallowing solid food, belching of gas, anorexia, loss of weight, marked salivation, and hoarseness of voice. In June, 1924, he complained of indefinite gastric symptoms and some difficulty in swallowing solid food. At the same time, the condition was diagnosed as duodenal ulcer, on indirect x-ray evidence. In spite of treatment the symptoms became more troublesome, particularly the difficulty in swallowing. The history of the next few months can be summarized as follows: the patient became progressively worse, and was, during this period, examined *de novo* by several physicians and a diagnosis of cardiospasm was made in all instances. The condition had progressed without remissions.

At the time of examination, no solids could be taken. There was no vomiting, pain, or regurgitation of food. Belching of gas and marked anorexia were prominent symptoms. The patient had lost twenty pounds in weight. He had always led a continent life, and had been in good health until the summer of 1924.

Physical Examination—The patient was a well developed male, somewhat pale, with evident loss of weight. The pupils reacted to light and accommodation. There were many carious teeth, the tongue was coated. No palpable supraclavicular glands were present. The lungs were negative. The pulse was 84, regular, of good volume and tension. Blood pressure systolic 125, diastolic 80. The heart was negative. The abdomen was full and soft, no organs or masses were palpable, there was no tenderness. Lymphatic, genitourinary, and nervous systems were negative. Rectal examination was negative, except for hemorrhoids. Urine, negative. Stools, occult blood on several occasions. The blood Wassermann test was negative.

Gastric analysis the tube failed to enter stomach. Bougies were passed without difficulty as far as 45 cm from the teeth. No obstruction was met with until the cardiac end of the oesophagus was reached.

Direct oesophagoscopy, July 2, 1925. Diagnosis stricture of the oesophagus. The pathological report on biopsy specimen taken from the lower end of the oesophagus, ran as follows: "There is no definite evidence of inflammatory reaction or of neoplastic proliferation."

X ray The patient was instructed to swallow barium in small sips. There was some delay at the cardia, the oesophagus was only slightly wider than normal. The lower end of the column of barium in the oesophagus showed a fine irregularity. Barium entered the stomach in constant small trickles and was caught in a small irregularity of the gastric wall on the lesser curvature just below the cardia. The retained barium remained there throughout the examination. The stomach was very small and lay entirely to the left of the spinal column. In the horizontal position, a walnut sized filling defect was seen on the lesser curvature near the cardia. This defect corresponded with the area of irregularity observed in the upright position.

On the grounds of persistent dysphagia without remissions, the presence of blood in the stool, and the X ray findings, diagnosis of carcinoma involving the lesser curvature and oesophagus was made.

Three months later, because of increasing difficulty in taking nourishment and the resulting marked emaciation, surgical intervention was decided upon. The operation was performed on August 27, 1925. It was with difficulty that the dome of the diaphragm was reached. There was a suspicious hardness around the lesser curvature of the stomach and the coeliac axis, probably invasion from the lower oesophageal growth. The fundus of the stomach was firmly fixed. A Witzel gastrostomy was done. A sipping from the lower end of the oesophagus was reported as "undoubtedly carcinoma", one from the growth of the lesser curvature was too small for diagnosis.

The patient did well for some time, then gradually declined, and died on November 26, 1925.

CASE 2

S. H., male, aged 45, first seen June 1, 1926.

Complaints—Pain behind the lower end of the sternum, on eating, difficulty in swallowing solids, accompanied by pain, eructation of gas associated with pain, increased salivation, loss of weight, loss of appetite.

Present Illness—Began two years ago. He complained first of a little pain behind the lower end of the sternum with every meal. Frequently, only the first swallow brought on pain and the pain disappeared with the taking of additional food. The pain did not

radiate and it was relieved by bicarbonate of soda. Gas eructations occurred, but no nausea or vomiting. The condition persisted for about two months and was followed by a remission of two months. During the subsequent eighteen months the patient suffered from recurrent attacks of pain, coming with the first swallow and disappearing with the taking of additional food. During the past six months the pain had increased in severity and was not relieved by food or medicaments. At the time of examination the patient complained bitterly of the pain behind the sternum which now came through to the back, and of painful gas eructations. Increased salivation was quite marked and a very troublesome feature. The appetite was poor, and because of the pain the patient feared to eat. The bowels were sluggish, there was at no time diarrhoea or melæna. The weight had gone down from 130 to 112 lbs during the course of the illness.

The patient had undergone three complete and separate examinations, with the following results: March, 1926 duodenal ulcer. He was put on a Sippy diet, was better for two weeks, but subsequently the symptoms returned. April, 1926 the examination was entirely negative for organic disease. The case was diagnosed as gastric neurosis. May, 1926 spasm of the lower oesophagus.

Personal History—The patient had suffered from asthma and constipation for twenty years. The asthma was cured two years ago. With these exceptions he had always been well.

Family History—Negative.

Physical Examination—The patient showed marked loss of weight, but was not cachectic. The pupils reacted sluggishly to light and accommodation. There were several capped and carious teeth and a moderate degree of pyorrhœa, the tongue was coated. Circulatory system. Pulse 100, regular, of fair volume. Blood pressure systolic 130, diastolic 80. Heart and lungs were negative. The abdomen was flat. There was slight tenderness over the entire abdomen. No masses or organs were palpable. The lymphatic, genitourinary, and nervous systems were negative. Rectal examination was negative.

Gastric analysis Fasting contents 10 cc, no food remnants, no blood. Free HCl was 0, total 16. At the end of one hour free HCl, 20, total, 40.

The urine was negative. Stool, dark brown, formed, with a faint trace of occult blood. The blood Wassermann test was negative. Blood hæmoglobin 90 per cent, red cells 4,900,000 per c.mm., white cells, 7,200.

Oesophagoscopy A specimen taken from the lower end of the oesophagus revealed inflammatory cells and a few suspicious cells, but no definite evidence of carcinoma.

X ray The barium suspension entered the stomach without being delayed at the cardia. The fundus was narrow and rigid. The barium could not be forced into it by pressure from below, a small quantity remained caught, and was distributed in an irregular manner in the fundus. The gas bubble was absent, but as the patient swallowed, a little air was seen in the fundus, this, however, quickly left the stomach and was belched up. Whenever this happened, the patient complained of pain behind the sternum. Peristalsis was active. The duodenal cap filled well. The stomach was empty in six hours. Examination of the colon revealed 72 hour stasis. Diagnosis infiltrating growth of the fundus, involving the cardia and causing insufficiency.

On July 29, 30 and 31st, the patient passed tarry stools. By this time he was confined to bed, and had lost considerable weight, he was taking very little food because of the pain and was losing ground rapidly. On August 5th, a Witzel gastrostomy was done. Operation revealed carcinoma of the fundus, involving the cardia, and extending posteriorly to the

pine, and adherent to it. The patient did not stand the operation well, and died on August 11, 1926.

CONCLUSIONS

In both cases errors in diagnosis were made several times. A survey of the literature on the subject reveals the fact that such errors are quite common. The apparent reasons for this have already been considered. If it is kept in mind that lesions of the cardia may give rise to œsophageal and gastric symptoms, and lesions of the fundus to œsophageal symptoms, much could be accomplished toward diminishing the number of undiagnosed cases, and toward making a correct diagnosis earlier.

Carcinoma of the fundus may give rise to œsophageal symptoms only. Such cases are particularly liable to cause errors in diagnosis, since all attention is centred on the œsophagus. Investigation reveals nothing but the presence of œsophageal spasm, and the disease is labelled "functional." Œsophagoscopy may reveal a little irregularity or bulging of the mucosa, but a specimen, taken even from an advanced case, may show no signs of malignancy. The spread of carcinoma is submucous, and unless a negative specimen includes a portion of the submucosa, no value can be attached to the findings. Lesions of the fundus may, by extension, involve the œsophagus, and those of the œsophagus may in a similar manner involve the fundus. Evidence is not lacking that the cardia does not serve as a barrier to the advance of malignant growths, either from the fundus upward or from the œsophagus downward. Furthermore, there is anatomical evidence that such extension does occur, and is quite frequent.

Malignant disease of the gastro-œsophageal junction is so unlikely to be limited to only one of the three situations under discussion, either in actual organic involvement, or in the development of symptoms, that it appears to be unwise to speak of carcinoma of the fundus, of the cardia, or of the last portion of the œsophagus. There appear to be sufficient grounds for referring to cancer of these areas as gastro-œsophageal cancer. A further advantage in the use of this term is that it simplifies the problem of classification, and incidentally makes the literature on the subject more readily available. The use of such nomenclature is sanctioned by precedent—*e.g.*, the term ileo-caecal tuberculosis.

SUMMARY

1. About 15 per cent of all malignant lesions of the stomach are situated at the fundus or cardia.

2. There is no definite symptom-complex pathognomonic of carcinoma of the fundus or cardia.

3. The tendency of malignant lesions of the cardia and fundus to give rise to gastric and œsophageal symptoms, respectively, is responsible for errors in diagnosis.

4. Dysphagia is the most important symptom,

and may not be directly due to the lesion, but to an associated spasm. A slowly developing dysphagia, progressively becoming worse, with remissions occurring early, if at all, is strong evidence in support of a diagnosis of malignancy.

5. Loss of appetite, gas eructations, and pain are the most frequent and early symptoms, but they are present in so many other conditions that they require only secondary importance.

6. Malnutrition, œdema, and loss of weight are late manifestations, and their absence does not constitute evidence against malignancy.

7. Enlarged supraclavicular glands are rarely present, and if present occur late.

8. Achylia and anemia are not reliable signs, but are of secondary importance. If present, anemia is a late manifestation.

9. Occult blood in the stools is an almost constant finding.

10. Œsophagoscopy is of little or no value as an aid to diagnosis, except in carcinoma beginning in the lower œsophagus, particularly in the presence of malignant ulceration.

11. The most important method of diagnosis is careful rhinoscopic and radiographic examination in all positions. The direct and indirect signs are enumerated.

12. The use of the term gastro-œsophageal carcinoma is suggested for malignant lesions involving primarily the terminal œsophagus, cardia or fundus.

ULTRA VIOLET RADIATION FOR THE GENERAL PRACTITIONER

By R. KING BROWN, B.A., M.D., D.P.H.
(III)*

In this article I propose to deal briefly with the question of lamps as a source of ultra-violet radiation. I shall not discuss the question of the best type of lamp to use from a purely scientific point of view, especially as the question from that aspect has by no means been settled, though many scientific investigators and clinicians have been and are still working at the matter. Further, as I intend my remarks to refer rather to the requirements of the general practitioner, and not to the hospital or public clinic, where the question of the consumption of electricity is not of such first importance, the economic side of the question will take a paramount, or at least an equal, place with the scientific side.

Most large hospitals generate their own current, and other clinics are assisted on the economic side in various ways, *e.g.*, out of voluntary funds, or by subscriptions or, in the municipal ones, out of the rates. With the general practitioner the matter is on a totally different footing. For reasons of space, time re-

* Article I, *Canad. M. Ass. J.*, March, 1928, xviii, 326; Article II, *Ibid.*, April, 1928, xviii, 465.

quired for supervision, the number of patients who can be treated simultaneously or within a given time, and the amount of current consumed, the type of lamp is most important. Provided he can be guaranteed a sufficient output of ultra-violet rays for his purpose, the purely scientific question of the close similarity or divergence of the spectrum from that of the natural sun is of secondary importance.

TYPES OF LAMPS

Lamps can be broadly divided into two main types, viz., (1) the open arc, and (2) the mercury-vapour lamp.

In the former there are two electrodes, and the current, in bridging the gap between the upper and lower electrode, produces a powerful flame which gradually burns up the ends of these. The variations in this type of lamp are usually due to variation in the composition of the electrodes. They may consist of pure carbon (upper and lower) which is a very common type, or the carbons may be impregnated with various metals such as sodium, magnesium, potassium, iron, tungsten or aluminium, or the cores may consist of the latter metals, or the electrodes may both consist of iron or tungsten, or one of the electrodes may be of iron or tungsten and the other of carbon. Sometimes pure tungsten is used, or more commonly an alloy, as pure tungsten is very expensive.

The carbon arc has been specially developed by the Finsen Light Institute of Copenhagen. The chief argument in its favour is that it produces a continuous spectrum more like that of the sun than any other type of lamp, and that consequently the output of ultra-violet rays, compared with the luminous and heat rays, is better balanced, thus obviating the necessity of supplementing the first-mentioned by lamps producing mainly yellow, red and heat rays. Carbon arcs, besides, do not deteriorate by using, the carbons, it is true, burn out, but as long as they are active the output of rays remains practically constant.

Against these advantages you have the large consumption of current. In the more powerful types 30 to 75 amps (3 to 7 B T U) per hour are required, and in the smaller type proportionately less, 15 to 25 amps ($1\frac{1}{2}$ to $2\frac{1}{2}$ B T U) being a common consumption. Another disadvantage is that they cannot be used in the open air as every draught disturbs the flame and causes the lamp to splutter a good deal. The tungsten arc produces a very large proportion of ultra-violet rays, but the electrodes are very expensive and require frequent renewal. It is a small lamp, simple in construction, but only adapted for special uses, and as I am considering the question of lamps more for general use, it need not be referred to again.

The second type of lamp referred to above is known as the mercury-vapour lamp. The mercury-vapour acts as a bridge of high resistance between the positive and negative poles, becomes intensely hot, and gives out a powerful light in which violet, indigo and green largely predominate in the visible spectrum, while the proportion of ultra-violet rays compared to the visible is very much greater than in the case of the carbon arc, more than 20 per cent of the ultra-violet output being between 3,900 Å U and 1,850 Å U. The mercury is generally contained in a sealed quartz tube burner, and the current (which must, as a general rule, be in one direction only) passes from the positive to the negative pole. If an alternating current be used it must be partially rectified so as to insure that it is unidirectional. There is another type in which the quartz tube is open to the air, with a suitable arrangement to prevent the mercury-vapour from getting into the air of the room. This type is said to be more easily cleaned and not to deteriorate so rapidly as the sealed form. A good representative of the former is the Hanovia quartz mercury-vapour lamp, and of the latter the K B B (Kelvin, Bottomley and Band) lamp. Both these lamps are air-cooled, but there are also water-cooled M-V lamps, such as the Kio-mayer. The lamp is cooled so that it may be pressed against the skin and the blood squeezed out, enabling the U V rays to penetrate more deeply in some cases.

The air-cooled sealed quartz mercury-vapour lamp is most used on the Continent, especially in Germany, where its properties have been and are still being carefully investigated. In a recent visit to Munich, Berlin and Hamburg, we found this type of lamp almost exclusively used in hospitals, public and private clinics.

The advantage of the mercury-vapour lamp of whatever type is that it only uses about one-fourth to one-fifth or less of the current required for the carbon arc, i.e., 3 to 5 amps per hour ($\frac{1}{4}$ to 1 B T U, or $\frac{1}{2}$ d to 2 d of electricity at 2d per unit power per hour), as against 10 to 75 amps per hour (1 to $7\frac{1}{2}$ B T U, or 2d to $1\frac{1}{3}$ per hour) for the latter, according to the size of the lamp. As stated above, the spectrum is very rich in ultra-violet rays, but the intensity or quantity, as distinct from the quality, of the different parts of the spectrum differs greatly both from that of the carbon arc and the sun. The range of ultra-violet light wave-lengths is much greater than that of the sun even on our highest mountains, but then intensity in proportion to the light rays below the green and the infra-red given out by them far surpasses the carbon arc or the sun. The intensity of their ultra-violet rays is also very uneven, certain groups being much more intense than others.

Peemoller shows this in another way. If you

take the Dorno rays, which are important therapeutic rays and lie between 3132 and 2894 Å in a mercury-vapour lamp at 220 volts alternating current (the strongest medical U-V lamp so far made is a 100 per cent unit) and test them with the Dorno cadmium cell you get the following results—

1 Mercury vapour lamp (artificial alpine sun, 220 volts alternating current)	100%
2 Peemoller lamp, carbon arc, aluminium core carbons horizontal	72.1%
3 Mercury vapour lamp, (110 volts direct current, artificial alpine sun)	11.3%
4 Peemoller lamp, carbon arc, cat. core, carbons vertical, max	13.5%
5 Carbon arc, iron core	14.1 to 7.2%
6 Old carbon arc with wick and homogeneous carbons	0.2%

Owing to the high intensity of the ultra violet rays in the quartz mercury vapour lamps the exposures to them are only about a quarter or less of those required by the carbon arc to produce an erythema. Thus doses of from 1 to 5 minutes, according to the condition of the patient as to pigment, use, etc. will correspond to from 5 to 25 minutes of a carbon arc. It is evident therefore that with the mercury-vapour lamp we have shorter exposures and can get through

a much larger number of patients in a given time. It is probably these factors which largely determined the preference of German and other continental workers for this type of lamp. Owing to their poverty in yellow, red and heat rays some clinicians make use of a heat-producing lamp—of which there are a number of useful models on the market—simultaneously with or immediately preceding the M-V lamp, so as to intensify the action of the latter. The method of using this will be discussed when we come to speak of the use of the lamp in disease in the next article.

One disadvantage of the M-V lamp is that the quartz burners when new give off much more intense ultra violet rays than when they have been a long time in use, owing to a rearrangement of the molecules of the quartz. When therefore they have been in use from 1000 to 2000 hours, they should be reburned. This is a somewhat expensive process and costs £3 or £4.

In the next article a short account of the technique of using the lamps will be given, and the diseases in which they so far have proved useful. (*The British Journal of Actinotherapy*, May, 1928, iii, 32)

Men and Books

RICHARD MEAD A FATHER OF PREVENTIVE MEDICINE

By W. H. HATTIE, M.D.

Halifax

In the summer of 1696, a new doctor made his appearance in Stepney, a young man who had just returned to his native town after six years of study at Utrecht, Leyden, Florence, Padua, Naples and Rome. At Leyden he had been the intimate friend and fellow student of Boerhaave. At all the places visited he had associated with men of various professions and had had opportunity to gratify and develop a native taste for literature and art. At Padua he had obtained the degree of Doctor of Philosophy and Physic. He had come back to England with a naturally engaging personality quite unspoiled, and able to adapt himself gracefully and easily to any social or other situation which might develop. Moreover, he was sagacious enough to appreciate the value of cultivating certain aids to success. And so he quickly acquired a clientèle and a reputation, and, as he found himself able to move from his original locale at Stepney to more and more

consequential locations, he came to be much discussed in medical and other circles.

Radcliffe, still in high fame and still crude in his bluntness, decided that this young man should be subjected to a crucial test. A dinner party was arranged and the aspiring young man was brought into the company of Radcliffe's most bibulous friends. The intention was to bring humiliation on him by making him highly intoxicated in the presence of his professional elders. But the young man was more wary than his elders, and presently the whole party with the exception of Radcliffe and his youthful guest were under the table. Any aversion which Radcliffe may have entertained vanished at once. "Mead," he exclaimed, "you are a rising man! You will succeed me!" Note now that Radcliffe was vain and Mead adroit. "That, sir, is impossible," Mead replied, "You are Alexander the Great, and no one can succeed Radcliffe. To succeed to one of his Kingdoms is the utmost of my ambition." "By the gods," said Radcliffe, "I'll recommend you to my patients!" And so the evening ended happily.

Next day Radcliffe called at Mead's office and discovered him reading Hippocrates. "Do you read Hippocrates in Greek?" he thundered

Modestly and fearfully Mead admitted that he did, greatly dreading that his scholarship would prove offensive to the great man. Radcliffe's air was sullen as he said "I never read him in my life." But Mead was again ready "You, sir, have no occasion. You are Hippocrates himself." The peril was past, and Mead was secure in Radcliffe's affection.

With this introduction to Richard Mead, let us investigate him a little further. He was born at Stepney, August 11, 1673. His father, Rev. Matthew Mead, a nonconformist minister and a writer on theological subjects, had been ejected from his charge some eleven years before, but possessed sufficient private fortune to maintain his family and to continue his ministrations to the nonconformists of Stepney. Eleven years after Richard's birth, the Reverend Matthew was suspected of designs against the government, and fled from Stepney to the safer place known as Holland. Up to this time, Richard had been tutored by another nonconformist minister (John Nesbitt), and now he was sent to a classical school kept by a former second master of Eton, Thomas Singleton, likewise a nonconformist. Under Singleton, Richard acquired a thorough grounding in Latin and Greek. At the age of seventeen he went to Utrecht, and, three years later, to Leyden. On completing his academical studies, he accompanied two celebrated gentlemen, (of whom one, Dr. Thomas Pellett, later became President of the College of Physicians) on the journeyings to which reference has already been made. Thus prepared, he returned to Stepney and to the house in which he was born, to begin his professional career and to associate himself closely with nonconformists.

Early in 1703, when he was not quite thirty years of age, he was appointed physician to St. Thomas's Hospital. This made desirable his removal from Stepney to a place more convenient to the hospital. A few years later he was astute enough to secure a house in Austin Friars, just vacated by the death of a busy practitioner. And when Radcliffe died (1714), the circumspect Mead, who had already acquired the major part of his practice, took possession of Radcliffe's mansion in Bloomsbury Square, actually before the burial of Radcliffe from his country place at Carshalton, where he had died. Some days before his death Radcliffe had presented Mead with the famous Gold-Headed Cane, which afterwards passed in succession to Askew, Pitcairn and Baillie the memos of which are so entertainingly related by MacMichael. So Mead succeeded Radcliffe, even as the latter had prophesied.

Mead, now about forty-one years of age, was thus firmly established. In the enjoyment of an income of between £5,000 to £6,000 a year—

in one year it reached £7,000—he was able to indulge his fondness for books and works of art, and to provide liberal entertainment for the host of prominent people who sought his friendship. Of these things we must say more later. Meantime it should be stated that his success was not due entirely to sagacious flattery and an instinct for sensing opportunity for material betterment. Once he had an urgent summons to attend a celebrated Duchess, and arrived at her home a bit unsteady as a result of somewhat free indulgence in the cup that both cheers and merrifies. While feeling her pulse his foot slipped awkwardly, and he confessed aloud "Drunk, yes, quite drunk!" The Duchess took this to be the diagnosis of her own condition, and told Mead that if he would keep her secret she would recommend him. Her recommendation aided his rise to fame and opulence. But, apart from all fortuity, Mead was a consistently hard worker, reader and thinker. Recognition of his qualities led to great demand for his services as practitioner and consultant. He wrote considerably, and several books have come down to us from his pen. The first of these, his treatise on poisons, appeared in 1702, and "De Imperio Solis et Lunæ in Corpora Humana" in 1704. In 1707 he was diplomated M.D. by the University of Oxford. Among other distinctions were appointment as lecturer in anatomy to the Company of Barbers and Surgeons, membership in the Royal Society, and fellowship in the College of Physicians. In 1744 he was offered the presidency of the college, but declined the honour.

During the last illness of Radcliffe, that physician to royalty was unavailable when Queen Anne lay on her death bed, and Mead was summoned in consultation. It will be remembered that the time was one of much intrigue. Three years before, Anne had wearied of her erstwhile favourite, the Duchess of Marlborough, and the great Duke also presently came into disfavour, the Whigs lost their domination, and the Tories gained the ascendancy at court, although the strength of the two parties was fairly well matched. The Tories favoured the Stuart Pretender, the Whigs looked to Hanover for a successor to the throne. Now that the Queen's demise seemed imminent, partisans of each side hovered about the court. It was important to the Stuart cause that the Queen's life should be prolonged, as the Pretender was abroad, while a representative of the Hanoverian house was on the spot. The court physician, though perhaps fully cognizant of the nearness of death, feared under the embarrassing conditions to tell the truth. Possibly, Mead might have gained favour with the Tories by a discreet silence, but possibly, too, he saw

advantage to the Whig cause (which he espoused) by frank expression of his opinion. At any rate he declared and made public his declaration that the Queen would not live an hour. The announcement was vital to the Jacobites who as we have seen needed time for the maturation of their plans and who seemingly accepted Mead's verdict as the death knell to their hopes. One historian comments: "It has always been considered that the prompt boldness of this political physician occasioned the peaceable proclamation of George I. The Queen's demise in one hour was confidently predicted by her Whig doctor. He was often taunted afterwards with the chagrin his countenance expressed when the royal patient on being bled, recovered her speech and senses." Perhaps the chagrin may have been feigned rather than real. At any rate we see Mead in the role of a political partizan almost that of a king-maker. Those who have read "The Gold-Headed Cane" will remember that Radcliffe good Tory that he was, was accused of having negatively murdered Queen Anne by declining to attend upon her and was threatened with assassination. Mead the Whig on the other hand, although suspected of having desired her death, does not appear to have incurred any popular disfavor by his association with the affair. This may be taken as further evidence of his adroitness.

One of the notable features of "The Gold-Headed Cane" is that it tells much more of other personages than of the characters it professes to delineate. At the risk of a similar offence, and at the further risk of making this paper too anecdotal, I venture to bring Radcliffe again into the story. Mead had noted that there was no Bible in Radcliffe's house, and was seemingly rather disturbed by the circumstance. In his tactful way he presented Radcliffe with a very beautiful Bible, formerly the property of King William, who had been a patient of Radcliffe's, as a memento of his late Majesty. Radcliffe, much pleased with such a gift, resolved to read the Book, and got as far as the middle of Exodus before his resolution failed. Had he gone farther he might have given his protégé other advice than that given in one of his confidences: "Mead, I love you, and I'll tell you a sure secret to make your fortune—use all mankind ill." We shall see that this advice was not accepted, and Mead chose rather, as much as in him lay, to live peaceably with all men. Other men, however, did not always choose to live peaceably with him. Some, perhaps jealous of his success, lampooned him without mercy. Such usually hid behind anonymity. But Woodward, Professor of Physic at Gresham College, attacked him openly, and in such an insulting manner, that Mead was infuriated and challenged him

to a duel. Accounts differ as to the skill displayed but Woodward was disarmed and ordered to beg for his life. "Never, till I am vomit-tired" was the happy retort which so appealed to Mead's sense of humor that the incident was at once ended. Gath's comment on this affair was: "Physicians if they be wise should never think of any arms but such as pen and ink."

In our day some at least of Mead's conduct would be considered to justify lampooning although it was seemingly not regarded as quite unprofessional in his time. Coffee houses were very popular resorts for the gossips of all grades of society and Mead followed Radcliffe's example by patronizing them and meeting there any apothecaries or other types or practitioners who wished to consult him. In the mornings he went to Tom's, in Covent Garden and in the evenings to Batson's, in Cornhill where he would advise such worthies in a half guinea per consultation, prescribing, therefore without seeing the patient. His usual fee for persons in good circumstances, was two guineas. It is related too, that he realized large sums by the sale of worthless nostrums. In other respects he seems to have lived blamelessly, though it is reported that he dabbled in stocks. It is not to his discredit that he was bequeathed two large fortunes.

Mention has already been made of Mead's earlier ventures in medical literature (1702-1704). Seemingly he was so engrossed with other activities that about sixteen years passed after the appearance of "De Imperio Solis et Luna" before another work issued from his pen, and this followed a request from the government to advise precautionary measures against the plague, then prevalent in France. Fifty years before, plague had caused 90,000 deaths in England, so its return was naturally dreaded. French physicians did not consider the condition to be contagious, and British commercial interests wished this opinion to prevail, but the government was doubtful. So, in 1720, Mead's advice was sought. After investigation he concluded that the condition was contagious, and set forth his opinions in "A Short Discourse Concerning Pestilential Contagion," which ran through seven editions in a year. In this he advised strict quarantine against infected countries and the isolation of infected towns, and to this extent was in agreement with the common usage of the time. But the practice of shutting up an infected house with all its inmates for a month after the disappearance of the disease he characterized as futile and cruel, and as favouring concealment. He advised that a Council of Health should be appointed for each town, charged with the duty of removing the sick to a distance of three or four miles from the town, and also of

cleansing and removing and supervising contacts. This was to be done at the public expense. In this we note the rudiments of provision for isolation hospitals and for asylums for contacts. Moreover, he urged cleanliness of streets and houses and avoidance of all unnecessary assemblies. He expressed little confidence in the fumigations which were popular, but made a partial reservation in favour of "the smoke of sulphur," which "abounds with an acid spirit which is found by experience to be very penetrating." Mead is credited as being the first to advocate a rational use of quarantine measures, and is spoken of as the earliest of the "Fathers of Preventive Medicine."

After the appearance of the "Short Discourse," another period of several years elapsed without literary productivity except for new editions of his first books. Meantime he was growing old, and felt the need for relaxation from the stress of so active a practice. He wished, moreover, for leisure to ponder over his experiences and to make use of his pen again. So he retired from much practice, and in 1747 brought out his "Treatise on Smallpox and Measles," written in Latin. He was then nearly seventy-five years of age, but, according to the author of "Lives of British Physicians," "the purity and elegance of style exhibited in this work have attracted the admiration of scholars." More than a quarter of a century before, impressed by the story of Lady Mary Wortley Montague, he had been a strong advocate of inoculation of smallpox, and had (1721), at the instance of the then Prince of Wales, afterwards George III (to whom he was appointed physician), experimented successfully upon several condemned criminals, who were pardoned after the demonstration. He and Friend (to whom we shall again refer) had urged that purgatives prevented or mitigated the severity of the secondary fever of smallpox. To this treatise he appended a translation of Rhazes, the only remaining Arabian MS. of whose essay was loaned to him by his friend Boerhaave for the purpose.

In the following year (1748) he published his "Medica Sacra," a literary curiosity which attracted much attention, in which he commented on the more remarkable diseases mentioned in the Bible and stated his belief that the demons mentioned therein were lunatics or epileptics. In 1749, he wrote "On the Scourge," and, in 1751, "Monita et Præcepta Medica," which is said to be the most important of his works. In this he discussed frankly his reflections upon his own experiences, and gave sage advice on the presentation of health of mind and body. This work is regarded as greatly superior to contemporary works of a similar kind.

It will be noted that much of his effort was in the nature of what we now term public health work. Further evidence of his interest in this field is afforded in his advocacy of a method of ventilating ships, etc., which was originated by Sutton. He interested fellow members of the Royal Society in this matter, and after ten years of persistent effort finally succeeded in inducing the Lords of the Admiralty to have the method introduced in all the ships of His Majesty's navy.

To hark back to his first book, that on poisons, Mead appears in it as one of the early votaries of experimental physiology. He provoked vipers to strike at hard bottles to secure venom which he injected into the veins of animals. He mixed venom with human blood in an endeavour to prove his theory that the effect of poison was due to mechanical action on the blood, a theory which he abandoned in a second edition of this work, published forty years after the first. He also tasted snake venom, in order to learn whether or no sucking a snake bite would be dangerous.

Mead was on intimate terms with the more noted of his medical contemporaries, notably Gaith, Arbuthnot, Friend, Sloane and Cheselden. Seemingly, he often demanded that Cheselden should be associated with him in consultation, especially if surgical questions were involved. We get an indication of this in these lines of Mead's intimate friend Pope:

"Weak though I am of limb, and short of sight,
Far from a lynx, and not a giant quite,
I'll do what Mead and Cheselden advise,
To keep these limbs, and to preserve these eyes."
—Pope, (*Imitations of Horace*)

But Mead's interests were by no means restricted to medicine. As has already been said, he had a great love for literature, for art, and for antiquities, and was an enthusiastic collector in all these lines. Some time after moving from Radcliffe's old house to a very pretentious residence in Omond Street (1719), he added a gallery for the accommodation of his library and museum (1732). This was a meeting place for all types of celebrities from all parts of the world, and "The Gold-Headed Cane" tells of some of these gatherings. Mead's linguistic accomplishments enabled him to converse with practically every visitor from abroad, if not in his native language at least in one with which both were acquainted. This fact, together with the certainty that a brilliant company would be met there, doubtless accounted in part for the extraordinary attraction of Mead's house for distinguished visitors to London. As he was well known to the literati, the antiquarians and the art-lovers of Europe, with many of whom he was in correspondence and with whom he exchanged curios and rarities, he would be well

advertised abroad. At least two of the crowned heads of Europe, the Kings of France and Naples, contributed to Mead's collection. The author of "Lives of British Physicians" (1830), tells us that Mead's "collection of statues, coins, gems, prints and drawings will probably forever remain unrivalled among private amateurs." In his library were to be found the most rare and ancient works, Oriental, Greek and Latin manuscripts forming no inconsiderable part. His pictures alone brought £3,400 at the sale after his death. He kept constantly in his employ several scholars and artists, who laboured at his expense for the benefit of the public. For his motto was "Non sibi sed toti." He "excelled all the nobility of his age and country in the encouragement which he afforded to the fine arts, and to the study of antiquity" (Lives of British Physicians). So it is not surprising that his house should have been a favourite place with those of artistic and intellectual tastes.

One of the pleasantest of the parties which met there is described by "The Gold-Headed Cane." Friend, who was a member of parliament had been sent to the Tower on being suspected of sympathy with Bishop Atterbury in his activities in behalf of the Stuart cause. Mead had been active in the endeavour to secure his release, but it was not until Sir Robert Walpole called him professionally that he made real headway. He would treat Walpole only on condition that Friend be given his liberty. And so it happened that the History of Medicine which Friend had commenced to write during his imprisonment was destined to be continued in more advantageous surroundings. On the evening of the day following his release, a large and distinguished party gathered at Whig Mead's to celebrate Toiy Friend's return to the world, when Mead presented Friend with the fees he had collected from the patients of the latter whom he had attended in his absence, amounting to more than 5,000 guineas.

Mead not only contributed freely to the institutions in which he was interested, notably the College of Physicians (for which he had executed the well-known bust of Harvey) and the Foundling Hospital, but his charity was unbounded, and he was ever ready to give his

services gratuitously. Among those who benefited by his free ministrations was a clergyman, a personal friend who officiated at one of Mead's marriages. After the ceremony this gentleman slipped away unnoticed, and Mead sent his brother to him with a handsome fee. To this the clergyman reacted as follows:

"To the Doctor, the Parson's a sort of a brother,
And a good turn from one deserves one from the other,
So take back your guineas, dear Doctor, again,
Nor give—what you so well can remedy—pain
Permit me to wish you all joy and delight,
On th' occasion that brought us together to night,
May health, wealth and fame attend you through life,
And ev'ry day add to the bliss of your wife."

Nor was Mead content with being himself a benefactor, but he influenced others to contribute of their substance to various good works. Conspicuous in this particular was his success in persuading Thomas Guy to spend much of his fortune in building of the hospital which bears his name.

It is not surprising that one of such artistic tastes should be inclined to live extravagantly. In addition to his elaborate city house, Mead maintained a country place near Windsor, to which he drove in a coach and six. He spent so freely and gave so generously that, notwithstanding the many years in which he enjoyed a large income and the legacies he had received, his estate netted only about £20,000.

Towards the end of his long life, his eyesight failed, and his physical and mental powers waned, but fortunately death came soon after these deprivations. He died on the 16th of February, 1754, at the age of 81, after five days of confinement to bed. He was buried in the Temple Church. In Westminster Abbey and in the Royal College of Physicians may be seen busts, suitably inscribed, of this wonderful man.

After his death, it was said of him, to quote The Gold-Headed Cane, "That of all physicians who had ever flourished, he gained the most, spent the most, and enjoyed the highest fame during his lifetime, not only in his own but foreign countries." And his contemporary and friend, Samuel Johnson, declared "Dr Mead lived more in the broad sunshine of life than almost any man."

The city of Nurnberg, among its many distinctions may claim to have been the place of publication of the first pharmacopœia, which was compiled in 1535 by Valerius Cordus, after consultation with the physicians

of the city. This work, at first restricted to galenicals, went through several editions. That of 1613 was revised by Minderer and was the first to admit mineral preparations.

of these notes that the subject of rheumatic diseases appears too often, but the many problems connected with this important group of disorders continue to attract great attention in this country. The Ministry of Health has just issued an important report on the provision of treatment for chronic arthritis, and at Bath, during last month, the large attendance of investigators, delegates and distinguished visitors from abroad, at a conference on rheumatic diseases, testifies to the interest shown in this subject. In his introductory address, Sir George Newman, Chief Medical Officer of the Ministry of Health, stated the problem, which was in point of fact how best to organize the campaign for the conquest or control of rheumatism. Out of the many papers which followed emerged many interesting facts divided broadly into those concerned with the social aspects, with the causation of rheumatism, and with the treatment of the disease. In the first place the economic burden of rheumatic infection is very large, and mortality statistics give little or no indication of the harm done to the community. Secondly, while we appear to know little about the exact causation, we know a lot about certain contributory factors and predisposing causes, and it should be possible to organize a "prevention campaign." Thirdly, treatment must be organized in efficiently equipped centres, with specialist "teams" and ample physio-therapeutic appliances. It is perhaps a pity that the acute rheumatic infections of childhood and the more chronic manifestations in adults were discussed at the same conference, for, partly because of the link by name, there is already too much muddled thinking about the connection, if any, between these two disorders. However, the conference was voted a great success and it is hoped that its fruits will soon be demonstrable.

Sunlight and Health—The month of May, except for its last few days, has been most depressing as far as weather is concerned and the opening of the London "season" has been marked by low temperatures, rain nearly every day and thunder storms from time to time. It may have been these factors which led the *Times* to bring out on May 22nd a big supplement called "The Sunlight and Health Number." It contains a lot of interesting material, especially about the discovery of vitamins, and the recent work on vitamin D and its preparation from ergosterol receive attention. "The days of darkness" writes the editor, "are also days of death and disease," and charts are shown which indicate the close relationship between the amount of sunlight and a low death rate. From October to March this rate is higher than for the other six months and it is during the summer that we store our sunlight for the winter. "In the early spring the

storehouse is tending to become empty" and it is therefore reassuring, during such weather as we have been experiencing, to know that "bottling sunlight" is an important British industry, and there is already on the market a large choice of ways in which we may keep our health until such time as the English summer, already a subject for mirth, arrives. Hope deferred need no longer make the heart sick, say the experts, if we take enough vitamin D.

ALAN MONCRIEFF

The Edinburgh Letter

(From our own correspondent)

A Famous Criminal Case—The news of the death of Madeleine Smith in the United States will stir many an old memory, recalling as it does one of the most famous of Scottish criminal trials. Madeleine was the eldest daughter in a highly respected Glasgow family, her father being an architect by profession, living in what was then a fashionable neighbourhood of the city. In 1857, when only twenty-one, she was charged with murdering Pierre Emile L'Angelier, who was ten years her senior, by poisoning with arsenic. L'Angelier was a clerk in a Glasgow office on ten shillings a week. This hopelessly ineligible suitor used to visit Madeleine clandestinely, first in her father's house in India Street, and later at Blytheswood Square. She seems to have been deeply infatuated with him and during their friendship wrote that remarkable collection of letters, which were exhibited in court and proved such a feature of the case. Subsequently she tired of him and wished to end an intrigue that was likely to interfere with the matrimonial plans formulated by her parents on her behalf. L'Angelier threatened to blackmail her by showing the letters he had received from her to her father. Madeleine appeared to take L'Angelier back to favour, and his visits were renewed. On March 23, 1857, L'Angelier died in his lodgings. A post-mortem examination revealed the fact that death was due to arsenic poisoning, 82 grains being found in his stomach alone. Madeleine Smith's letters were found in his rooms. She was arrested and charged with poisoning her lover, by giving him on three different occasions a cup of coffee containing arsenic, through the basement window of the house in Blytheswood Square. At the trial the letters were produced and caused a deep impression, not only by their passionate appeal, but also by their conspicuous merit. The speeches on both sides were brilliant. That by John Inglis, the Dean of the Faculty of Law, in her defence has long been considered a model of excellence. The distinguished beauty of the accused, the despicable character of the deceased, and the fact that poisoning trials are rare in Scotland, stirred public opinion to the

utmost. After a trial which lasted nine days, during which Madeleine was the most self-possessed person in the court, the jury returned the eminently fair and cautious Scottish verdict or 'non-proven'.

"All Great Britain," states F. Tennyson Jesse in the *Trial of Madeleine Smith*, 'was agitated over the trial, and there were three points of view held by three different schools of thought. There were strong pro-Madeleinites who contested that she was innocent, and that L'Angeher had committed suicide, equally strong anti-Madeleinites, convinced that murder had been committed by her, and that she should pay the penalty, a third school, in which probably most students of the case have found themselves ever since, which declared in effect—'Probably she did it, but anyhow he deserved it'."

Madeleine Smith, the chief actress, was possibly the last survivor of that intensely moving drama, the last act of which was fought out in the High Court in Edinburgh. The eminent counsel, the witnesses, the spectators who fought for admission, must mostly have been gathered to their fathers. Yet, still, we meet people who will give you their impressions of the case, (they always seem to have known some one who was present,) discuss the pros and cons, and tell you what they pretend to know is the correct solution of this unsolved mystery. Prejudice dies hard. One meets few Madeleines in Scotland. Even now it is not a popular Christian name to give to a baby girl. And, as though it boded ill omen, silk, the material she wore during the trial, is said to have suffered a severe slump for many years afterwards. So much for 'old wives' tales'. Whether she did, or whether she didn't, the old lady has guarded her secret well, in the seventy-one years of obscurity which have elapsed since, in all her youth and beauty, and apparently unmoved, she faced her terrible ordeal.

The Royal Edinburgh Maternity Hospital—It is one of the features of the voluntary hospital system that management committees always seem to be asking for money. At the annual meeting of subscribers of the Royal Edinburgh Maternity and Simpson Memorial Hospital, Baillie, Dr Nasmyth, in an appeal for funds so urgently needed, pointed out that the number of deliveries in the hospital during 1927 was 2,094, which constituted a record in its history. Taking the total of indoor and outdoor cases last year, the gratifying fact was disclosed that 38.6 per cent, or more than one-third of the whole births of Greater Edinburgh, took place under the supervision of the staff of this old established institution. The antenatal clinics continued to grow in popularity and usefulness. During 1927, 10,000 visits were paid to these clinics. As a natural growth of the antenatal work, the post-natal clinic was now in

action. More than 1,000 visits had been paid to it since its inception in February, 1927, and the results had been most satisfactory. The hospital had maintained its front rank position as a midwifery school. During the year 83 nurses and 287 medical students had been trained. Dr Nasmyth referred to the proposed amalgamation of the hospital with the Royal Infirmary. The site of the proposed extension of the Infirmary, which is at present occupied by George Watson's College for boys, will not be available for some time, but, when it is, the new Maternity Hospital will occupy one of the finest positions in the city. Dr Nasmyth asked for a stabilized annual income of £40,000, to enable the hospital to carry on the excellent work in the same manner as it has been doing during the last eighty-three years.

A New Sanatorium—They never do things by halves in Glasgow. Work is now proceeding on a £500,000 sanatorium, to accommodate 464 patients. Ground for this institution was acquired at a cost of £17,000 at Mearnsburn in 1913. Owing to the outbreak of war the proceedings were interrupted. It is expected that the sanatorium will be completed and ready to receive patients by 1930.

Appointment—At a meeting of the University Court, Professor Alfred E. Cameron, Professor of Zoology and Entomology in the University of Saskatchewan, was appointed Lecturer in Medical Entomology in the Department of Natural History, as from October, 1928.

Veneral Diseases—The Edinburgh Corporation Veneral Diseases Bill failed to receive a second reading in the House of Commons. The object of the Bill was to give the Corporation compulsory powers in relation to the treatment of venereal disease, enabling them to deal effectively with defaulters who had failed to continue treatment. The main fear of those opposing the Bill was that compulsion would again drive the disease underground, and ruin all the success of the Voluntary System. Sir John Gilmour, the Secretary of State for Scotland, advised the House to reject the Bill. His speech settled the fate of the Bill, which was defeated by 156 votes to 95. On top of this comes the announcement that the corporation of the City of Glasgow have adopted a Bill for the prevention, notification and treatment of venereal disease. The Bill seeks powers more drastic than the recently rejected Edinburgh Corporation Bill. It was pointed out that compulsory treatment is being gradually forced on local authorities, and it is estimated that there are 100,000 sufferers from this disease in Glasgow, of whom 75 per cent are innocent cases.

Research in Animal Breeding—The constitution of the animal breeding committee to be set up by the University Court of Edinburgh, in connection with the Department for Research in Animal Breeding, has now been approved by

the Board of Agriculture and the University Court. The University Court have taken over the financial responsibility for the department, and are now taking the necessary steps to constitute the committee. The new institution in connection with the department is on the south side of the City of Edinburgh. There, some thirty acres of land are at present used for the maintenance of experimental animals. The department uses six laboratories in the chemistry building of the University, which is in the immediate vicinity. Lord Woolavinton recently donated £10,000 towards the endowment of a chair of animal breeding in the University. The Department has been in existence on a small scale since 1920, and recently received an offer of £30,000 from the International Education Board, contingent upon a further £30,000 being provided by the University and other private sources. Work has been done in connection with the study of sheep's wool, and experiments have been undertaken to investigate the inheritance of various colours and patterns. A malformation of the limbs of newly born lambs, who either are born dead or die shortly after birth, has been found to be hereditary. An analysis of the Clydesdale breed of horses has been continued. Investigations dealing with superfetation in pigs, and the increase of winter milk production in goats, and various other subjects, have also been in progress.

GEORGE GIBSON

THE MODERN METHOD OF PRESCRIBING

To the Editor

The contribution of Dr. O. S. Gibbs on the Modern Method of Prescribing in your May Journal is of considerable interest to pharmacists.

It is bad enough to have one system of weights and measures for buying and selling and another for dispensing prescriptions, without having all the complications that arise out of differences between the Imperial and American systems in both of these circumstances, and on top of that the metric system in the pharmacopœias.

It would help the situation greatly and indeed would be a godsend to pharmacy, if medical practitioners would abandon the apothecaries' system and adopt the metric.

Three or four dollars would buy all the metric weights and measures needed for dispensing, and "converting" from one system to another would soon cease so far as dispensing pharmacy is concerned. The big difficulty arises in the learning of metric doses by prescribers. Every pharmacist is taught the metric system.

The change would not involve as much difficulty as some imagine. It does not take

long for one accustomed to pounds, shillings and pence to learn the value of dollars and cents. The metric system is exclusively used in general science, and is being increasingly employed in medical texts. So much so, that readers who cannot "visualize" metric quantities are under a serious handicap. This would be overcome so far as medical men and pharmacists are concerned in a very short time, if metric prescription writing were to become general.

Your editorial comment on Dr. Gibbs' article seems to imply that the only objection to "single dose" prescriptions is the burden of multiplication placed on the dispensing clerk in the drug store. This burden is more imaginary than real, since it is one of the functions of a dispenser to check the doses of a prescription, he shares with the prescriber in the legal responsibility for any injury that may occur through an excessive dose. Multiplying is surely not more difficult than dividing, which must be done in determining the dosage.

As it is, the dispenser is accustomed to single dose prescriptions in powders, pills, etc., and this type of prescription would be no more difficult in mixtures. It probably would be less of a burden on the dispenser to complete the quantities to be mixed from a single dose prescription than upon the prescriber to complete the quantities to be written for a "multiple dose" prescription.

The former type is more simple and its general adoption where applicable would tend to remove the uncertainty that sometimes occurs as to the quantity a prescriber desires.

G. A. BURBIDGE,
Chairman of Council,

Canadian Pharmaceutical Association

Halifax, May 25, 1928

INNERVATION AND TUMOUR GROWTH

To the Editor

In July, 1927, my book "The Cancer Mystery Solved" (London, The C. W. Daniel Co.) was published and on sale. In the book, I show that the nervous system performs a vitally important part in tumour formation and growth, including that of cancers, which are dealt with in "a complete series of comprehensible steps." On the cover of the book occurs the following: "The author of this book claims to have elucidated the origin and nature of cancer, and to have brought to his support evidence strong enough for proof. He shows that the rôle of the nervous system, in cancer production, has been almost entirely overlooked, notwithstanding that cancer only occurs in vertebrate animals."

On February 17, 1928, there appeared in the *Liverpool Echo* an article headed "Nerves in

Human Cancers" "An Important Canadian Discovery" The article was cabled from Montreal, and was stated to be "According to an official statement from the McGill University Pathological Institute" The article went on to show that, according to the statement, Dr Horst Oertel, Director of the Institute, working with associates, had succeeded in establishing the fact of the presence of nerves in human cancers "This," says the statement, "has so far not been recognized, and has even been denied by high authorities on cancer"

On February 18, 1928, I sent an explanatory letter, a copy of my book on cancer, and a cutting from the *Liverpool Echo* containing the article, "Nerves in Human Cancers" to a recognized and accepted authority on medical ethics and practice In his reply, he said, "I have received your letter of the 18th of February with a cutting from the *Liverpool Echo* of the 17th of February, and also a copy of book, 'The Cancer Mystery Solved' The announcement in the *Liverpool Echo* refers to an official statement from the McGill University Pathological Institute, and to an article by Dr Oertel, the Director of the Institute, to appear in February issue of *Canadian Medical Association Journal*

"This statement claims that the presence of nerves in human cancers and other malignant tumours has so far not been recognized, whereas your book, published in June, 1927, deals with that subject in detail

"In these circumstances I think your proper course is undoubtedly to write to Dr Oertel, challenging the accuracy of the official statement, and pointing out the real facts"

In the course of his letter, he also advised me that in certain circumstances it might be advisable and necessary to publish my claims in the medical press

On February 21, 1928, I wrote Dr Horst Oertel, Pathological Institute, McGill University, Montreal, Canada, challenging the accuracy of the report issued by the Pathological Institute My letter to him was registered, and I also sent him a copy of my book on cancer by registered post I have had no reply Meanwhile, I have had great difficulty in obtaining a copy of the February number of the *Canadian Medical Association Journal*, and have only recently succeeded in so doing Dr Oertel's article is entitled "Innervation and Tumour Growth," and begins thus "In searching the vast literature on tumours, only occasional and fleeting references concern nerves in relation to tumour growth Even in the larger, comprehensive works this matter is dismissed with a few words Accordingly, the nervous system appears as of little, if any, account in the development and life of tumours" It is quite evident these views are

in need of drastic revision In the same connection, I may point out, that in 1921 in the *British Medical Journal*, I wrote that cancer probably owed its initiation to loss of normal trophic nerve influence caused by an irritant, and not to the action of the irritant on the cells themselves, as many generations of cells die off and are replaced by fresh cells before a local irritant causes cancer as a rule Shortly after my article appeared in 1924, there was a meeting at the Medical Institute, Liverpool, to discuss Dr Young's microbial theory of cancer At this meeting (reported in *BMJ*), Prof Paul of Liverpool, expressed the opinion, in view of his extremely wide surgical experience, that the nervous system was an important factor in cancer formation My book on cancer goes in minute detail into the initiation and mode of growth of all tumours, including cancers, and shows exactly the rôle of the nervous system in their formation and growth

It is very interesting, as it adds further concrete proof to my thesis on cancer, to see, according to Prof Oertel's article, that, "Prof Beattie, formerly of University College, London, now of the Anatomical Department of McGill, who kindly looked over some of these slides, tells me that these finer fibrils remind him of the embryonic nerve branches in the development of the stomach I leave for the present undecided whether this has any particular significance in regard to growth of immature tumours"

Dr Oertel will see from my book that this embryonic appearance of the nerve fibrils is, in fact, of the very greatest significance

Referring again to Prof Beattie, Prof Oertel proceeds, "He has also drawn my attention to an article by C J Hill (*Phil Trans Roy Soc*, London, Series B, 1927, ccxv, 335-387), which shows in some illustrations (notably 27 and 28) of terminal epithelial nerve ramifications between and around cells in a villus of small intestine of a new-born rabbit a resemblance to some of our own tumour preparation"

This also is further confirmatory proof of my thesis that preliminary to tumour growth there is always precedent degradation of the nerve fibrils supplying the involved tissue cells—the injury to the nerves being caused by local anaphylactic reaction over a period of time

Dr Oertel in the concluding remarks of his article says, "Indeed, the conception of 'independence' and 'autonomy' in tumour cells, if these observations are further substantiated, will have to be modified or interpreted accordingly"

As regards this, I contend that the primary cellular conception of cancers and other tumours, which for so many years has un-

fortunately been held inviolable, which has for so long held back the advance of knowledge in these matters and has thus been the cause of a vast amount of unnecessary misery and suffering in vertebrates generally, was finally and irrefutably destroyed when my book was published in 1927

Yours faithfully,

42 Bentley Rd, ANDREW S McNEIL
Liverpool, May 21, 1928

To the Editor:

I have read the letter of Dr Andrew S McNeil of Liverpool, which you were good enough to send me

Anyone acquainted with the questions involved will at once see that his reasoning and assertions are confused, and not at all to the point. In a small book (which I enclose) under the title "The Cancer Mystery Solved" he has advanced no new facts or even scientifically founded theories, but has rather naively conceived and phrased his assumptions as regards the causes and origin of cancer and other tumours. In regard to the rôle of nerves, more particularly, he has simply repeated, in somewhat modified form, an old idea in "loss of trophic nerve control to the parts affected," and he makes much of what he calls "nerve degradation" — ~~the factor~~ ^{the factor} on tumour growth. This factor he includes amongst other postulates (six altogether), which I shall quote to you, in order that you may understand his mentality (page 38): "(1) General tissue poisoning (re-arranging of molecular elements), (2) Local tissue reaction (caused by local irritant), (3) Local anaphylactic reaction (plus a weak general anaphylaxis), (4) Altered trophic nerve control to the part affected, (5) Loss of trophic nerve control to the part affected ("Cancer"), (6) General tissue reaction. (In successfully resisted tumour growth, the successive weak general anaphylactic reactions—just as in asthma of childhood—overcome the general tissue-poisoning or 'sensitization,' and so stop the anaphylactic reactions, local and general. If the tumour is not of the very primitive type, the general body tissues, by general tissue reaction, can now treat the tumour as an ordinary inflammatory swelling, and absorb it)"

Further on, he makes these statements (p 45): "(As tumours are poorly supplied with blood-vessels except in certain cases where tumours originate in vascular tissues, it is very likely that all the nerves to the part—including the vaso-motor nerves—suffer damage by the local anaphylactic reaction, but this aspect we shall not further consider)"

"The cells are not yet completely out of control of the damaged trophic nerves, but are in a state of unstable equilibrium. As the trophic nerve fibres become more primitive in type, through losing their covering, owing to the continued anaphylactic reactions caused by the continuing intermittent local irritation, so do then 'orders' to the cells supplied by them become more primitive. The cells themselves become more primitive, divide more rapidly, and finally, when the uncovered trophic fibrils succumb to the continued local anaphylactic reactions, the pressure of the growing tumour cells, and the juices elaborated by them, the tumour cells are quite out of control, the tumour has become completely 'autonomous' and is now classed as a 'cancer'" (!)

I need not make any comment on these statements. But in any event, the rôle which the author assigns to the loss of nervous control in regard to tumour growth is not a new one, for this is a hypothesis which has been advanced, in different modifications, by various authors since the celebrated experiment made under Schröder van der Kolk, laid down in an inaugural dissertation in 1834, to whom Vichow refers in his work on tumours in 1863, page 61. Amongst later authors, Rindfleisch and Borst have also emphasized the possible relation of lack of proper nerve regulation (a local tissue weakness) as regards tumour development, and the commonly accepted idea of the absence of nerves in tumours has been put forward as a support of these hypotheses.

With all such hypothetical ideas our work has nothing to do! It does not deal with any theory of tumour formation, but it records a definite morphological finding of newly formed nerves in tumours. (Consult in this connection the Editorial in *The Lancet*, March 24, 1928. The importance of such a finding in relation to the present ideas of cancers is there properly stated). Indeed, we are still engaged in further confirming and extending these findings, and it may be added that the very demonstration of newly formed tumour nerves removes much support of ideas which bring "lack of tissue organization" or a "local nerve weakness" or "loss of control," or "nerve degradation" (whatever these indefinite phrases may mean), into direct connection with tumour growth.

While Dr McNeil advances a general hypothetical conception of the origin of cancer, I cannot find that he has in any way carried on investigations on the actual demonstration of tumour nerves, or even furthered our knowledge of tumours. Even less can I see how he can find, as he states, anything in our researches to confirm his views in his thesis that "preliminary to tumour growth

there is always precedent degradation of the nerve fibrils supplying the involved tissue cells—the injury to the nerves being caused by local anaphylactic reaction over a period of time” (Page 5 of Dr McNeil’s letter to you)

The question which concerned us is not, I repeat, one of theory, but of fact—namely, *do tumours actually possess nerves of their own?*

Much more could be said in serious criticism of Dr McNeil’s own writing, and his rejection of the important contributions from others as regards experimental tumour growth, but I think I would only try your patience, and enough has been said to show his inability to grasp the issues about which he quarrels. I have not answered his letter, nor have I taken notice of his book, for the simple reason that I did not consider an answer of any useful purpose. His letter to you only confirms my opinions.

Sincerely yours,

HORST OFTEL,

*Strathcona Professor of Pathology,
McGill University, Montreal*

June 11, 1928

THE PROVINCIAL MEDICAL BOARD OF NOVA SCOTIA To the Editor

On page 761 of the issue of the *Canadian Medical Association Journal*, June number, appears this item:

“During the last session of the Provincial Legislature, an Act was passed amending the Medical Act. Previously the Board was constituted of nine members appointed during pleasure by the Government, and six members elected by the Medical Society of Nova Scotia for periods of three years. As amended, the Government appointees will hold office for three years, but will be eligible for reappointment, and the Government may remove any members of the Board upon due cause being shown. In April, Drs M. A. MacAulay, E. V. Hogan, Halifax, J. A. Sponagle, Middleton, M. Sullivan, Glace Bay, J. W. McLean, North Sydney, E. E. Bissett, Windsor, F. C. Lavers, New Ross, J. C. Morrison, New Waterford, were removed from membership on the Board by Order in Council, and the following were appointed to the vacancies thus created: Drs O. B. Keddy, Windsor, Hon. W. N. Rehfuss, Bridgewater, W. N. Cochran, Mahone, F. R. Little and John

Rankine, Halifax, B. E. Goodwin, Amherst, Allister Calder, Glace Bay, Hon. B. A. LeBlanc, Arichat
W. H. HATTIE”

One rather significant and peculiar detail, for some reason, seems to have been missed by your correspondent, viz., that Dr J. J. Cameron of Antigonish, one of the older members of the Board appears to have escaped the general slaughter, and still remains a Member of Provincial Medical Board of Nova Scotia, while others, who were appointed at the same time and since, were summarily dismissed, no reason or explanation being vouchsafed. Dr Cameron had long passed the three year period, and the Government, to be consistent, should have cancelled his old commission, as was done in the case of the other eight, and then re-appointed him, if they so desired.

It may be of interest to the profession generally to know just how this thing was done. On or about April 20th of this year notices were sent out to the various members of the Board by the Acting Secretary, to attend a meeting, on May 11th. Three days after notices of dismissal were received by eight members of the Board.

No one, so far as I know, was advised of any change in the Act, nor given an opportunity to tender his resignation. Ordinary courtesy, and the usual amenities of life, one would think, would have suggested to the Government that, with this proposed re-organization (if it ever really materializes), a letter of explanation would have been in order. Evidently, the representatives of our profession on the Provincial Medical Board were regarded, in much the same light as highway employees, registrars of births and deaths, etc., and were entitled to no more courtesy or consideration. The Nova Scotia Government, in their methods of dealing with this matter, have established a record discreditable to themselves and not approved of by right-thinking members of our profession, irrespective of their political affiliations.

Yours truly,

J. A. SPONAGLE

Middleton, N.S., June 15, 1928

N.B.—It will be noticed that the Government appointed two of themselves.

“Too early specialization is one of the great faults of modern American education. The medical school is not the place for the training of specialists. The specialist who has not had a good basic medical training is a danger to society.”—Dr W. S. Thayer, President, American Medical Association.

Rochet and Peycelon record the rare event of an aneurysm of the splenic artery, of syphilitic origin, which caused death by rupture into the stomach. The aneurysm was so deeply situated as to be undetectable by palpation.—*Lyon Médical*, 1927, vol xxxiii

Topics of Current Interest

STUDIES IN THE RELATION OF HEREDITY TO CANCER*

BY MAUD SLYE

Chicago

Experiments in the nature and behaviour of cancer have been carried on in the cancer laboratory at the University of Chicago during the past eighteen years. All studies have been with spontaneous cancers arising in the natural life of the animals exactly as man's spontaneous cancers arise. The autopsies have now numbered over 65,000, including between 5,000 and 6,000 primary spontaneous cancers. These tumours have included practically every type and location of tumour known in human pathology.

These studies have demonstrated that hereditary predisposition bears a definite relation both to the tendency to be exempt from cancer and the tendency to be susceptible to it. In thousands of mice bred in the laboratory, the tendency to be exempt from cancer was transmitted as a simple dominant trait along mendelian lines.

Results of Cross Breeding—When a cancer-free mouse was mated with a cancerous mouse, none of the first generation offspring had cancer. The tendency to be exempt from cancer thus behaved like a simple mendelian dominant. If, however, two of these first generation hybrids were mated, one-fourth of their offspring were susceptible to cancer, while three-fourths were exempt from it. Thus the tendency to be susceptible to cancer behaved like a simple mendelian recessive.

If instead of mating two first generation hybrids each first generation hybrid was mated with a cancer-free mouse, no cancer appeared in the second generation. In this manner, that is by mating all first generation hybrids with cancer-free mice, all cancer susceptibility has been ruled out of the entire family for many generations. Thus the tendency to exemption from cancer is unquestionably inheritable. Many hundreds of strains and branch strains have been carried in this laboratory, which have never shown a tumour growth of any kind, either malignant or benign. This means that in many families, carried for fifty or more generations and comprising thousands of members, there has been complete exemption

from cancer. Those cancer-free mice, when bred into other families, carry with them exemption from cancer as a dominant character. Compare this with the record of man who pays no attention to heredity in his matings, and where one in eight over a certain age is dying of cancer, and note how tremendously hopeful is this fact of the inheritability of the tendency to be exempt from cancer.

The tendency to be susceptible to cancer is also inheritable, but it is inheritable as a recessive character. This means, that even though there is a great deal of cancer on one side of the family, even to 100 per cent, if there is no cancer in the other side of the family, all the children will be cancer free. If they in their turn mate with cancer resistant individuals, cancer should be eliminated from their immediate families also.

There are apparently two factors necessary for the production of cancer, first, the inherited susceptibility (that is susceptible soil), and second, irritation or chronic stimulation of the type fitted to induce it. In mice susceptible to only one location of cancer, no amount of irritation or stimulation applied to other parts of the body has ever to date produced a cancer. Avoidance of irritation to the locally susceptible tissues has prevented cancer even in susceptible individuals.

Susceptibility to cancer has proved to be local and not systemic. This means that if an individual susceptible to cancer will protect himself against irritation of locally susceptible tissues, he may avoid cancer even though he is susceptible. If every individual knew his heredity, as the heredity of those mice is known, and knew to what type and location of tumour he was susceptible, he might avoid the type of irritation fitted to induce the disease, and thus avoid it, even though he were a member of a 100 per cent cancer family.

The fact of the inheritability of resistance to cancer is one of the few hopeful observations ever made concerning this disease, because it means that, instead of every one being susceptible, large numbers are exempt. This is certainly a most encouraging fact, and it should be allowed to lift the fear of possible cancer from those who are by heredity exempt from it. It also means that it should be possible wholly to eliminate cancer by the appropriate genetic procedure. This does not mean that we can yet relax our vigilance against all forms of chronic irritations in any case, since we have not as yet even begun to apply the facts of heredity to the human species. But it

* Abstract of an address given by Maud Slye, Associate Professor of Pathology, University of Chicago, at the Third Race Betterment Conference, Battle Creek, Michigan, January 26, 1928.

does mean that we should begin to take steps to make such an application, and that in this procedure lies much hope.

Moreover, since there is in man the beginning of a genetic sense, (that is a sense for the fitness of matings) it should be possible to educate this sense. *This is the great hope for humanity.* The way to educate it is to make generally known the facts and operation of heredity, so that man need not be blind as to what characteristics he is transmitting to his children. Thus, it should become possible wholly to eliminate such diseases as cancer.

It therefore, we would uniformly permit examination after death is is the invariable rule in this laboratory the exact facts concerning disease in man could be obtained. If these facts were then kept in permanent record as every fact is kept in permanent record in the laboratory, in two generations by the right matings, just as I have eliminated the disease from hundreds of families in the laboratory, so it may be possible to eliminate cancer from human families.

THE VALUE OF A CREDIT BALANCE IN YOUR VITAL ASSETS ACCOUNT

People have no doubt been very much comforted in the past ten years by frequently hearing the statement made that in the last fifty years, fifteen years have been added to the life of man.

This statement is unfortunately somewhat misleading, inasmuch as it can be demonstrated that this saving occurs for the most part during the first twenty years of our lives, and in fact the greatest saving is during the first year.

Obviously then, what is meant by this statement is not that fifteen years have been added to all of our lives, but that the expectancy of human life has been increased, as the result of the activities in the field of preventive medicine, during the first two decades of life.

The so called wasting diseases of middle-life—that is, cancer, chronic heart disease, chronic Bright's disease, premature hardening of the arteries, apoplexy—have not been influenced by the activities in public health and preventive medicine. This is largely due to the fact that these diseases come on so insidiously that their presence is not suspected until they are far advanced, oft times approaching a fatal termination, unless they are revealed as the result of examinations for life insurance, or, as during the Great War, by medical examining boards.

However, within the past few years there has been a rude awakening. We know now that many cases of heart disease, kidney disease, premature hardening of the arteries

and apoplexy can be traced back to early infections following an acute communicable disease, and later on to syphilis or focal infection from the tonsils, teeth, accessory sinuses in the head, chronic diseases of the appendix prostate, gall bladder or from the large intestine.

These degenerative diseases of middle life are responsible for over 40 per cent of our total death rate every year, and have not only been uncontrolled but are increasing year by year.—*Health Bulletin*, Toronto, May 5, 1928.

LABORATORY METHODS IN DIAGNOSIS

Although the very proper effort to establish more and more firmly the scientific basis on which the art of medicine rests must inevitably tend to emphasize the academic aspect of medicine it would be disastrous if this were to bring about any slackening of endeavours along the line of clinical observation. In an address on diagnosis (*Brit M J*, 1928, 1, 335), Dr Robert Hutchison suggests that as a result of the increased facilities for laboratory and other investigation which are to some extent intended to apply the findings of academic medicine to practical uses, there is to-day some deterioration in bedside observation as compared with former days. If this indeed be so, it behoves us to be careful, for modern educational demands require an increasing amount of time to be spent in the laboratory, and presumably (unless familiarity is to breed contempt) an increasing attention to laboratory methods.

The question therefore arises, Is there really any reason why laboratory methods, even if multiplied far beyond those in use to-day, should divert attention from the clinical study of disease? The answer is certainly in the negative, if only the nature of the information these laboratory methods afford is clearly recognized. On this point, however, there appears to be a good deal of misapprehension, and even Dr Hutchison seems perilously near error when he speaks of "laboratory tests *and other* short cuts to diagnosis" (italics ours), though his whole argument makes it abundantly clear that for him, at least, there can be no such short cuts. Laboratory workers, like other specialists, are apt to be over-enthusiastic about their own branch of work, and to attach undue weight to the information they are able to give, but no laboratory method yet devised can provide a short cut anywhere, on the contrary, it can only put another fact at the clinician's disposal, and so increase the number of data, whose value it is his business to assess in coming to a considered opinion. But laboratory methods do provide facts, and it is here that the clinician is sometimes at fault, for if the laboratory finding is not in harmony with his clinical conception of

the case he is apt, especially in his teaching, to draw distinctions between "clinical observation" and "laboratory methods" which are by no means flattering to the latter. This is all wrong, there is no real distinction between the two types of observation.

The fact that a patient has an eosinophilia, a raised blood urea, or a positive Wassermann reaction, is merely a clinical observation which it happens to be more convenient to make in the laboratory, but if we were to take the necessary apparatus to the bedside, such investigations would in no essential way differ from those made, say, with a stethoscope or a thermometer, and the information they give is much of the same order. Viewed in this light laboratory methods merely give additional clinical facts. Occasionally it may be a fact which dominates all others, but far more often it is one which, fitting into its place with others in the mosaic, helps to complete the diagnostic picture. Sometimes, indeed, the fact is one for which no place can be found, but this should not be made a ground of complaint against laboratory methods, it is merely evidence of our present ignorance. In the early days of the Widal reaction it was

sometimes a complaint that the reaction was negative in a clinically clear case of typhoid fever, but the subsequent recognition of the paratyphoid organisms proved the accuracy of the laboratory work, and doubtless much that seems contradictory to-day will be made plain by the knowledge of the future.

It is, however, not to be denied that danger lurks in too great emphasis upon the importance of the laboratory, and it would be an interesting experiment if, during some part of their career, students could be prevented from access to all reports from special departments, and were made to rely entirely on their own investigations. For some minds there is a curious attraction about facts elicited from a test tube or by the microscope, as being more scientific than those observed by the unaided senses, and this is a prolific source of error. The sensible plan seems to be to collect all the facts that are within our reach by whatever means they are obtained, and then, taking Dr. Hutchison's wise words to heart, pray that we may be granted the supreme diagnostic gift—a right judgment in all things.—*Brit M J*, 1928, 1, 361 (Editorial)

Abstracts from Current Literature

MEDICINE

The Value of the Electrocardiogram in Acute Rheumatic Fever Reid, W. D., and Kenway, F. L., *New Eng J Med*, Mar 15, 1928, cxcviii, 4

As is the case with other chronic progressive diseases, it is highly important to detect the earliest signs of involvement of the heart in acute rheumatic fever. Increased attention is being paid to the condition of the myocardium from the earliest stage of this disease, and the electrocardiograph is being employed to help in the detection of derangements of the heart muscle.

A series of 26 cases of rheumatic fever in the Boston City Hospital have been studied from this point of view, three types of changes being especially looked for, namely (1) increase in the auriculo-ventricular conduction time, (2) alteration in the ventricular complex, (3) various irregularities in rhythm. Repeated electrocardiograms on the same patient were taken in order to detect the changes, since these are often transient.

The findings of these authors indicate that the heart muscle is affected in a large proportion of cases. There was an increase of

auriculo-ventricular conduction time in 92 per cent, in 42 per cent of which it took the form of partial heart block. Change in the ventricular complex was detected in 80 per cent, and extra-systoles in 34 per cent. These findings correspond with the reports of other observers.

It is important to note that evidence of myocardial development is found even when the arthritis has completely disappeared and the heart appears normal on physical examination, not only that, but the electrocardiogram may be the first and only evidence of cardiac involvement. There seemed to be no relation between the duration of the joint symptoms and the degree or persistence of the electrocardiographic changes.

This high incidence of changes in the electrocardiographic examinations confirms the opinion which is now widely held that the heart is involved in all cases of rheumatic fever, even if there are no clinical signs of the involvement. It also is in accord with the conception that whilst the arthritic changes are exudative and may be checked with salicylate medication, those in the heart are proliferative and may progress in spite of what appears to be improvement clinically.

H. E. MACDERMOT

Some Points in the Early Diagnosis of Diseases of the Central Nervous System in General Practice Adams, D K, *Glasg Med J*, May, 1928, etc

Many practitioners of wide experience might be inclined to say that organic nervous disease is hopeless, a point of view which depends mainly on the fact that exact diagnosis is so difficult in this type of disease. In no other branch of medicine do so many similar pictures or disease arise from different causes, or a single etiological factor give rise to such dissimilar clinical conditions. A broad survey shows however that most organic nervous diseases fall into one or other of three main groups, neuro-syphilis, disseminated sclerosis, and epidemic encephalitis. Cerebral tumours are comparatively much fewer than any of these, but still form a fourth important group.

The most important point in dealing with these is their early detection, and yet Dr Adams holds that rarely if ever are they diagnosed in their earliest stages. In the case of neurosyphilis text-book descriptions rarely conform to what is seen in practice, and certainly not to what is taking place in the very early stages. If the diagnosis depends only on finding Argyll-Robertson pupils, abolished knee-jerks, and Kernig's sign, it is not to be expected that treatment can be of much avail, in spite of therapeutic agents of such power and specificity as salvarsan.

Among early symptoms transient diplopia is of first importance. Dr Adams in a large series of cases has only twice found this to be without an organic basis, and in both these cases there was a high degree of astigmatism. Inequality of pupils, irregularity in outline, impairment of consensual reflex to light, slowing and fatigue of the light reflex, are all changes that may precede a fully developed Argyll-Robertson pupil. Ptosis or gradual development of a squint are highly suggestive.

Derangement of bladder function is another early symptom. It may take the form of frequency, precipitancy, hesitancy, or retention. Crises also are frequently early in appearing. Reference is made to the frequent mistaking of these for acute abdominal conditions. Such patients often present no other signs of tabes. Other forms of crisis, such as the laryngeal, must also be borne in mind. Dr Adams cites the case of a young man in whom a tracheotomy was performed for symptoms of urgent asphyxia, which were later shown to be a laryngeal manifestation of neuro-syphilis. In this case the pupils were normal and the knee-jerks brisk, but close questioning brought out a history of previous double vision, frequency and precipitancy of micturition, and girdle pains.

Disseminated sclerosis is the next commonest organic nervous disease in Europe. With all its many resemblances to neuro-syphilis it almost certainly has no etiological relationship with it, although there is evidence to suggest that it is due to a non-syphilitic spirochæte. In this disease also it is quite evident that when the clinical signs have become as definite as given in the text-book, paraplegia, intention tremor, nystagmus and slurring speech, the damage to the brain and cord must be extensive and irreparable. Of the early symptoms transient diplopia, especially in a young healthy adult, is of very grave significance. Temporary loss of sight is another important sign. It is due to a retro-bulbar neuritis and may improve in a few weeks, hence the likelihood of its being passed over as "idiopathic."

One of the most constant early signs is loss of abdominal reflexes. Derangement of bladder function is as common as in neuro-syphilis and as in that disease is an important early symptom.

The treatment need not be regarded with the hopelessness which it commonly arouses, if the disease be recognized early. Even after allowing for the spontaneous remissions which characterize its course, much may be done with artificially produced pyrexia, mercury and salvarsan.

As regards epidemic encephalitis Dr Adams has a less optimistic view. It is noteworthy that with each epidemic recurrence it has shown fresh manifestations which tends to make the diagnosis extremely difficult at times. It may be confused in its severe forms, with tuberculous meningitis, or cerebral tumour. The Wassermann reaction should serve to separate it from cerebral syphilis. Only too often it is only by the subsequent development of Parkinsonism that encephalitis is finally recognized. So far no really hopeful treatment has been evolved. The suggestion that a dietetic factor is partly responsible is worthy of investigation.

The conclusion is that in nervous diseases early recognition is essential for successful treatment, and such recognition can be achieved only in general practice. It is with the general practitioner that the hope of real advance lies, as it does in most fields of general medicine.

H. E. MACDERMOT

An aid to the Early Diagnosis of Measles and Possibly Various Other Eruptive Diseases Wadsworth, W M, and Misenheimer, E A, *J Am M Ass*, May 5, 1928, etc, 18

The authors noticed, while using ultraviolet radiation for a child who had just recovered from measles, with disappearance of the eruption five days before, that exposure to ultraviolet rays in a darkened room made visible what seemed to be a generalized eruption on

the trunk, face and limbs. They then made observations on the effect of exposure to these rays in cases of measles in the pre-eruptive stage, and in the first case observed they found that the eruption showed beneath the epidermis exactly 48 hours before it became visible microscopically. A total of 14 cases were observed under these conditions, and it was found that the rash appeared at times varying from 33 to 76 hours after it became visible under the ultraviolet rays. The 76-hour case was a child of two years whose condition was followed from the beginning of the fever. It was found that the rash is present somewhat earlier in blondes than in brunettes, also that it becomes visible sooner in babies than in older children. The average seemed to be about fifty hours.

This method was tried in one case of scarlet fever and the rash showed plainly 11 hours before becoming visible to the naked eye.

The authors feel that this way of determining the presence of a rash before it becomes apparent should be of considerable value in settling the diagnosis in the earliest possible stages. They refer to two cases in which the patients had been exposed to measles and had high fever, but in whom the ultraviolet ray failed to show any rash, thereby reversing an original diagnosis of measles.

They suggest that this may be a useful aid in determining the time at which it is safe to discharge a case of measles, as the rash is plainly visible on exposure to the rays for a number of days after its apparent disappearance. Eruptions in other diseases also, such as variola, syphilis, typhoid fever, would probably be detected and confirmed by this means.

II E MACDERMOT

A Case of Erythredema or "Pink Disease"

Cunne, D L, *Brit M J*, 1928, 1, 48

This disease is sometimes called erythredema polynucleitis, and seems to be quite rare. The author's case was in a boy aged two years and eight months. The disease began with malaise and occasional vomiting about two weeks before the more serious manifestations. Then the child developed intestinal colic, with slight elevation of the temperature. The bowels were constipated. Three days later photophobia and conjunctival injection were noted, and the child was completely hypotonic. The tips of his fingers and toes were now slightly reddened, swollen, and painful to the touch. The next day he became semi-comatose, and his fingers, toes, and the greater part of his hands and feet were bright red, swollen, and acutely tender. Wasting was rapid. Three days later, improvement was noted, his temperature began to fall, the red oedema was less marked. Then, the affected skin began to peel, complete casts of some of his fingers being shed in one piece. As he convalesced he was

noted to be quite weak, his legs were wasted and flabby, and the knee-jerks were absent. It is suggested that "pink oedema" is a polynucleitis due to an intestinal toxæmia.

Fatal Poisoning by Borax

Buch, John, *Brit M J*, 1928, 1, 177

The case recorded by Mr. Buch has so many points of similarity with that described by Mr. Donald Cunne under the name "erythredema" or "pink disease," noticed above, that it raises the important point whether poisoning by borax or boric acid may not account for the latter rare affection.

A child, two weeks old, was found to be unconscious, extremely emaciated, and with the eyelids closed. All four extremities were markedly flexed at all joints. The respirations were irregular, the heart-beats were normal. The temperature was subnormal. The fingernails and terminal phalanges of the left hand were coloured a bright red, as if painted, the forefinger was red and swollen as far as the wrist, in marked contrast to the fingers of the right hand. The coloured fingers were tender. A red ring surrounded the anus, the entire scrotum and the lips had the same abnormal colouring. A spot of red was visible at the external extremity of the right upper eyelid. The feet were normal. The bowel washings had the "cooked spinach" appearance described as occurring in Mr. Cunne's case.

During the previous five or six days the infant had consumed about one and a half drachms of borax and boric acid, in the form of honey and borax and glycerin of borax, administered to prevent thrush on the advice of a nurse. The child died three days later, when seventeen days old. There was post-mortem staining of the same colour. The muscles and arterial blood were pink. Not much else was found. The stomach contained about one ounce of a thin, yellow, opaque substance resembling honey. The liver and kidneys were dark, the latter being congested with spots of hæmorrhage under the capsule.

The author suggests that many cases of obscure illness in infants may be due to the administration of borax. A dummy teat, dipped in glycerine of borax may carry $1\frac{1}{2}$ to 2 grains of borax, all of which is swallowed.

A G NICHOLLS

Thoughts on the Morbid Processes Active in Pernicious Anæmia

Kumbhaari, E B, *Am J Med Sc*, April, 1928

The disease is more than a matter of cell destruction, the increase in hyperplastic hæmopoietic tissue is much greater than the increase in blood destruction. It would seem that a more fundamental defect of the hæmolytotoxic system may be the inability to form

efficient erythrocytes. Why are these cells unfit? It seems that some substance in the liver interrupts the pernicious process in the bone marrow and allows it to settle down to a normal activity.

There is a question as to whether the active liver substance is a vitamin, hormone, detoxicant or still some other kind of agent or whether it merely replaces something absent or deficient in the pernicious anemia liver. Whipple has advocated the view that pernicious anemia is a deficiency disease due to a deficiency in materials that build the stroma of the erythrocyte. That the spleen is also concerned is indicated by the prompt improvement that usually follows splenectomy. In addition to the hemolytic function it may have an influence in preventing the liver from exerting a maturing effect on the erythroblasts.

Achlorhydria is probably a constant but preceding and otherwise unrelated accompaniment of the disease. The chief types of causative agents that have been advanced are some unknown intestinal ptomain, a chronic cholecystitis, a hypersplenism, a disturbance of lipid metabolism with an accumulation of hemolytic unsaturated fatty acid. It is safe to say that none has ever approached proof just as one can say that the real disease has never been produced experimentally.

From the evidence at hand and *a priori* reasoning, one leans toward an intestinal noxa somehow associated with achlorhydria and absorbed by the portal system. This hypothetical noxa may in turn in its passage through the spleen stimulate it to excessive hemolysis, as well as damage its normal relation to the hemopoietic function of the bone marrow. Arriving in the liver, it may upset that organ's hypothetical relation to hemopoiesis (perhaps hindering it in furnishing a necessary ingredient) with the result that inefficient erythrocytes are prematurely ejected into the blood stream or their maturation delayed and disturbed, so that in spite of the marrow hyperplasia an insufficient number of inefficient erythrocytes are turned out, to be destroyed in excessive numbers, as is well recognized in the pathological anatomy and physiology of the disease.

LILLIAN A. CHASE

The Ten Year Diabetic What He Is What He Should Be How to Make Him So Joslin, E P, *Am J Med Sc*

At present the ten-year diabetic is one whose disease began when he was between 15 and 68. Most frequently his disease has begun in the fifth decade. Frequency 22 per cent of the total cases have lived 10 years. There is good reason to predict that every diabetic will be a ten year diabetic soon. We have had insulin only five years.

Tenth diabetic anniversaries. The celebration of the tenth diabetic anniversary is cheering to the patient as well as to the doctor. It promotes morale. Last year the mortality of the 1,205 cases seen and traced was 35 per cent but for the 235 children it was 13 per cent.

Causes of death. Approximately half the deaths in last year's series of 42 deaths were from cardiovascular and renal conditions. Save for cancer 0.47 per cent, the other causes of death were scattering and had little connection with diabetes. Only one case in 42 died of tuberculosis. Arteriosclerosis has replaced coma as a cause of death. Studied by Roentgen ray it is found in every necropsy upon a diabetic, young or old, of five years' duration.

The average age of diabetics at death. The average age of diabetics at death has increased from 44 $\frac{4}{5}$ years in the Naunyn period to 60 $\frac{9}{10}$ years in the last twelve months.

Diabetes is milder the longer it lasts. Formerly diabetics were expected to get worse, now they get better. As the duration of diabetes lengthens, its symptoms should lessen and fade away.

What he should be. If over thirty-five he should be of normal weight and the finest product of the periodic health examination. How to make him so. By the early diagnosis of diabetes. To discover diabetes early seek for it in the obese between 45 and 55.

The prevention of arteriosclerosis. Never overfeed a diabetic, least of all with fat. Protein should be moderate, more than 1 gm per kgm of body weight in the young and less than 1 gm in the old. Hyperglycemia does not seem to be a cause of arteriosclerosis. Until it is proved that cholesterol in the blood of diabetics is low, it is wise to give few rather than many eggs. Apart from eggs, the quantity of cholesterol in food is comparatively low. Cholesterol is essential and is to be found in practically every cell of the body. Do we manufacture it or eat it only ready made? Can we destroy it or merely excrete it and can we hasten its excretion when it is present in excess? All these questions should be investigated soon.

LILLIAN A. CHASE

Diphtheria Prophylaxis Among Asthmatic Patients Waldbott, G L, *J Am M Ass*, Jan 28, 1928, xc, 4

The potential dangers attending the injections of horse serum in the case of asthmatic patients are too well known to call for any re-statement. It might therefore be expected that the employment of diphtheria toxin-antitoxin amongst those with asthmatic histories would be frequently attended with dangerous consequences, but in practice this seldom appears to be the case. A great many asthmatics have been given toxin-antitoxin injections without

showing any untoward symptoms, even when they show specific reactions to horse serum.

There is therefore a considerable discrepancy between the theoretical aspect of the causation of asthma and actual experience in the use of these injections containing protein, but, whatever the explanation may be, it cannot be said that no danger exists. Cases, few though they may be, have been reported in which alarming and even fatal results have followed the injection of toxin-antitoxin in the presence of a sensitivity to horse serum, and now Dr. Waldbott draws attention to a series of cases of severe asthma, whose symptoms were definitely brought on again, and in a much aggravated form, by the injection of toxin-antitoxin serum for the prophylaxis of diphtheria.

He makes two suggestions as to avoiding this danger. One is that in this type of patient the serum should be detoxicated as in Ramon's anatoxin, or Larsen's ricinoleate preparation, thus obviating the use of horse serum. But even in these preparations there are proteins of various kinds, and they may be capable of precipitating asthmatic attacks in those who are susceptible. It is therefore suggested in addition that small desensitizing doses of serum should be given to these patients before the whole injection is given, and this is probably the safest course to pursue in every case.

H. E. MACDERMOT

Le Groupe Sanguin II de l'Homme Chez le Chimpanzé Human Blood (Group II) and the Chimpanzee. *Ann. de l'Institut Pasteur*, 1928, xli, 363.

This author, in a most interesting and suggestive article, has investigated the blood group reactions in man and the chimpanzee. He begins with a short résumé of the work done on precipitins, agglutinins and hæmolysins in the past, comments on the confusion to the literature in regard to the nomenclature of the various blood groups, to remedy which he suggests that an international conference should take up the matter. He then defines his own nomenclature, and gives a valuable statement in regard to the percentages of the different blood groups in many races of mankind. He points out that the laws of Mendel apply to the different blood groups, and, following von Dungern and Hirschfeld, Ottenberg, Dycke and Pluss, considers the cellular agglutininogen to be the dominant character.

The following are the author's findings —

1 The red corpuscles of the chimpanzee (14 animals tested) are agglutinated by human sera III (B) and IV (O), human sera (AB) I and II (A) are without action on these corpuscles.

2 The serum of the chimpanzee agglutinates human red cells I (AB) and III (B). It has no action on human cells II (A) and IV (O).

3 The blood of chimpanzees, then, presents the blood characters (agglutininogen A and agglutinin B) of group II in man.

4 Man, of group II, can receive with impunity intravenously the citrated blood of the chimpanzee.

5 This identity of cells and sera in the case of the chimpanzee and man of group II tends to support the hypothesis of the common ancestry of chimpanzee and man.

A. G. NICHOLLS

Neue Versuche über Immunisierung mit Abgetoteter Pockenvakzine (A New Method of Immunization with Devitalized Small-pox Vaccine) Knopfmacher, W., and Stohr, D., *Monatschr. f. Kinderh.*, 1928, xxxvii, 4.

These observers have found that by repeated injections of small amounts of cow-pox vaccine heated to 56° C, so as to devitalize and attenuate it, it is possible in many cases to produce immunity against cow-pox. In young infants three injections of one gram of such an avirulent vaccine produce a certain protection against subsequent skin inoculations with the regulation vaccine.

The glycerinated lymph is diluted with physiological salt solution in the proportion of 1:2 or 1:5, and injected, preferably at intervals of five days. This method is recommended in the case of children exposed to the danger of contracting small-pox, who are not, for any reason, suitable subjects for the ordinary small-pox vaccination.

A. G. NICHOLLS

SURGERY

The Present-Day Status of Operative Treatment of Ulcer of the Stomach and Duodenum Haberer, H., *Deutsche Zeitschrift für Chirurgie*, 1927, cc, 212.

Surgeons to-day are by no means agreed upon the proper operative treatment of gastric and duodenal ulcer. Broadly speaking, there are two schools of thought upon this subject, one conservative, the other radical. Followers of the conservative school recommend palliative operations and short-circuitings. Supporters of the radical line of thought insist upon complete removal of the primary lesion together with a considerable portion of the stomach itself, and re-establishment of gastro-intestinal continuity by one of several methods.

From a study of 2,100 cases operated upon by himself Prof. Haberer places himself unreservedly in the group of "radical" surgeons. He has performed resection 1,698 times for ulcer of the stomach or duodenum. He summarizes his views and reviews the advances of the past decade as follows.

There are to-day no generally-accepted rules for the selection of the most suitable operative

procedures in the surgical treatment of ulcer but guiding principles can be laid down along general lines. At the present time radical surgery seems to offer more promise of a successful result than conservative methods. Resection, however, cannot be designated as the operation of choice in the hands of all surgeons, on account of the difficulties of the procedure. The less experienced and less skilful workers will show better results with gastroenterostomy than if resection be attempted, especially when the local conditions present great difficulties. Even the most radical exponents of resection cannot dispense with gastroenterostomy as the proper procedure in inoperable ulcer, whether the inoperability depends upon the extent of the disease or the condition of the patient.

Or the indirect or palliative methods, gastroenterostomy always gives the best number of post-operative jejunal ulcers. Pyloric occlusion in any form is to be abandoned, as it accomplishes no more than simple gastroenterostomy, and has a much higher percentage of subsequent jejunal ulcers. Further studies are required to determine whether simple jejunostomy shall be given a definite place as a method of ulcer treatment. There are two weak points in all palliative operations. First, they do not with certainty lead to the healing of the ulcer, and thus do not protect the patient from the complications of ulcer (bleeding, perforation, cancer). Second, it is not always possible at operation to distinguish between cancer and ulcer. Mistakes are possible in at least 5 per cent of cases.

Or the radical methods the sleeve resection has been discarded by many surgeons on account of the few satisfactory permanent results obtained and the danger of the recurrence of the ulcer. It cannot be employed as the method of choice in ulcer of the stomach. Billroth's resections with removal of the pylorus give good results if the whole acid liberating mechanism is removed. Radical resection can thus be avoided. In resection the most important fact to keep in mind is the frequency of multiple ulcers. Many so called recurrent ulcers following resection will not stand critical examination, but must be considered as true ulcers overlooked by the operator through ignorance or incomplete technique. It cannot be denied, however, that true recurrences can take place.

A definite number of jejunal ulcers have occurred following Billroth II. Their number can be reduced by faultless technique, but can not be entirely abolished, because the method does not re-establish the normal physiological relations of the parts. Pyloric glands scattered in the first part of the duodenum may explain some of the jejunal ulcers after Billroth II. The resection according to Billroth I has the

advantage over Billroth II that it retains the normal physiological relations. Apparently it is not followed by jejunal ulcer. It is, however, much harder to carry out than Billroth II, and the number of cases in which it can be used is much smaller. Of late the method has been extended by the introduction of termino-lateral anastomosis between the cut end of the stomach and the mobilized descending portion of the duodenum (Habeier's operation).

The only proper treatment of jejunal ulcer is its radical resection. Billroth I has here the same advantages as Billroth II. In carcinomatous degeneration the operation must naturally be carried out as early as possible.

Chronic recurring bleeding from ulcer demands operation before anemia brings an irreparable damage to parenchymatous organs. Acute hemorrhage demands immediate operation, if a previous diagnosis of ulcer has been made and its situation is known. There may be multiple ulcers, and bleeding may recur after one lesion has been dealt with at operation. In acute hemorrhage in a patient in whom an accurate diagnosis has not been made operation may fail to reveal an ulcer, and the patient will only be harmed by the procedure. In such cases conservative treatment is indicated. Blood transfusion is of greatest service. Operation is demanded in acute perforation. The general condition of the patient and the ability of the surgeon will decide whether conservative or radical treatment shall be carried out. In properly selected cases resection in the hands of experienced rapid operators gives the best results. Primary closure of the abdomen is desirable. In gradual perforation expectant treatment is indicated. When the symptoms have subsided one can operate with greater safety than in the early period when abscesses are often encountered, and radical operation prevented.

R. R. FITZGERALD

Surgery of the Large Intestine. Pool, E. H., and McGowan, F. J., *Am. J. Surg.*, March, 1928, iv, 245.

Most of the lesions of the large intestine, not including the rectum, are situated in the cæcum and must be considered as possibilities in the study of the average chronic case. The authors discuss in this paper tuberculosis, actinomycosis, carcinoma, intussusception, mesenteric obstruction, Hirschsprung's disease, diverticulitis, colitis, amœbic dysentery and polyposis.

Tuberculosis—Localized tuberculosis of the colon is more frequent than is usually supposed, often goes unrecognized, and has as its most frequent sites the cæcum and ascending colon. The most significant type is the hyperplastic, resulting in marked thickening of the wall and relatively little ulceration. The

symptoms suggest chronic intestinal obstruction, slowly developing constipation, with periods of diarrhoea. On examination with a barium enema the characteristic filling defect of hypertrophic tuberculosis is a complete absence of barium at the site of the lesion, differing in that respect from carcinoma. Other lesions than carcinoma are difficult to differentiate, even at operation, such as inflammatory conditions about the appendix, or actinomycosis.

When stenosis has developed operative relief is indicated and when the lesion cannot be differentiated from carcinoma the treatment should be the same as for cancer. In general, however, the treatment should be conservative, for intestinal tuberculosis can heal completely when treated by heliotherapy, which must be continued intensively under expert direction for many months.

Actinomycosis—This fungus selects the ileo-cæcal region as the usual site and results in a slow chronic inflammatory reaction, causing marked thickening of the intestinal wall, later involving adjacent structures, including the abdominal wall and retroperitoneal tissues. When the sinuses develop through the abdominal wall the fungus may be recognized in the scant pus. In the early stages the lesion may be mistaken for carcinoma, hyperplastic tuberculosis, or chronic inflammation dependent on the appendix, and the true nature cannot be recognized at operation. Therefore, resection is the appropriate procedure, but later, when fistule and infiltration have occurred, radical operation is useless.

Carcinoma—The colon is a frequent and relatively favourable site of cancer, favourable, because it is limited in extent, slow in growth and late in metastasizing, the secondaries for a long time being confined to the regional lymph-nodes. Various histological types of cancer occur, and the advantage of slow growth is often sacrificed by late recognition. Frequently, the palpation of a mass, or the onset of intestinal obstruction, are the first symptoms. Suggestive symptoms are blood in the stools, abdominal discomfort, and bowel derangement. Any or all of these symptoms should lead to a persistent investigation to seek their cause. Pain or discomfort of a colicky nature may be the first complaint. The sigmoid is the most frequent site, then the cæcum then the ascending colon. If involving the right half of the colon, diarrhoea usually occurs for a time, whereas constipation is usually associated with involvement of the left colon.

The authors emphasize two general details of diagnosis: first, the importance of a routine rectal and sigmoidoscopic examination, second, the danger of administering barium by the

mouth in cases of suspected obstruction, thereby converting a chronic into an acute obstruction.

With regard to treatment before obstruction resection is the rule. In the right half of the colon this should be in one stage, but in the left half a two-stage operation is infinitely safer. In acute obstruction palliative procedures should always be elected, *ie*, drainage above the obstruction. The diseased bowel is not favourable for an anastomosis and the toxæmia of obstruction renders the patient intolerant of prolonged operation.

Important features in the surgery of carcinoma of the colon are early operation, early recognition of obstruction, and relief of retention.

Intussusception—This should be diagnosed if a child, between six and twelve months old, has sudden, severe, colicky and intermittent abdominal pain with vomiting. The vomiting occurs early. Blood and mucus are passed *per rectum* after the bowel contents have been evacuated. Abdominal palpation shows a sausage-shaped tumour, not always in the right ileo fossa, which may be palpable *per rectum*. Early operation is essential.

Mesenteric Obstruction—Mesenteric obstruction is due either to embolus or thrombosis of a mesenteric vein. Diarrhoea with blood in the stools and indefinite abdominal symptoms often precede the more serious symptoms of obstruction. If operation is performed early, results are usually satisfactory, later, the condition is usually fatal.

Hirschsprung's Disease—Two-thirds of the cases involve all of the colon, in the others the dilatation is confined to the pelvic colon. The symptoms are marked constipation from infancy and abdominal distension, with a characteristic picture given by the x-ray. Treatment is irrigation of the bowel followed, if not satisfactory, by cæcostomy or resection.

Diverticulitis—The sigmoid is by far the most frequent site and, as a rule, the diverticula do not give rise to symptoms until the onset of an inflammatory reaction. This inflammatory reaction simulates that of inflammation of the appendix and, on account of the slowness of the inflammatory progress, abscess with walling-off is the rule. Chronic symptoms occasionally occur, giving rise to repeated attacks of discomfort in the lower left quadrant, with frequent and inadequate stools. Diagnosis is confirmed by the x-ray examination.

The significant features of diverticulitis are that it is a disease of adult life, with left sided symptoms similar to acute or subacute appendicitis, and the inflammatory process goes on to abscess-formation. The treatment, when the symptoms are acute, is operation, when abscess is formed, drainage being instituted and nothing else.

Colitis—Colitis presents the symptoms of pain, diarrhoea with blood in the stools, tenderness along the site of the colon and sometimes fever. The course is protracted, and in severe cases anaemia is marked, resulting in the patient becoming extremely weak and prostrated. Amœbie and tuberculous ulcerations must be excluded in the diagnosis. Treatment on the basis of recent studies includes, besides local measures, correction of distant foci of infection and the use of vaccines. If surgery is resorted to a caecostomy is indicated.

Amœbic Dysentery—This disease may involve the whole large intestine, but the caecum is the favourite site. The ulcers are characteristic, with a small opening on the mucous membrane leading to a cavity in the submucous coat, hence the term "flask shaped." The symptoms resemble those of colitis, but the diagnosis in this condition depends entirely on the finding of amœbæ in the stools. The results with emetin are excellent.

Polypoid—The structure of polypoid tumours is that of an adenomatous hyperplasia of the intestinal mucous membrane, resulting in hæmorrhage, and diarrhoea, with a marked tendency to malignant change. Palliative treatment is unreliable, resection is rarely successful, on account of the extensive and low distribution of the lesions.

R. V. B. SMITH

The Precancerous Changes in the Rectum and Colon. Lockhart-Mummery, J. P., and Dukes, C., *Surg., Gynec. & Obst.*, May, 1928

One of the greatest difficulties in studying the etiology of cancer is that the disease is seldom seen in the early stages of development. Thus the changes in the normal epithelium which result in malignant tissue are still but little understood.

In the vast majority of cases of rectal cancer there is nothing in the patient's history which points to any previous condition acting as a forerunner. There does not appear to be any relationship between hæmorrhoids, internal or external, and carcinoma. Pruritus does not act as a forerunner, as it does in the epithelioma of the vulva, but chronic fistula does occasionally appear to act as an exciting cause. Chronic constipation appears to be without importance, and it must be admitted that, apart from adenoma, we know of no condition in the rectum which predisposes to cancer with any frequency.

It is evident that the etiology of malignancy cannot be elucidated by the histological study of tumours, and that one must go farther back and examine changes in the epithelial cells before malignancy is reached. This is a difficult procedure, because it is hard to obtain suitable material, but, just as Sir Lenthal Cheate has recorded the relationship of chronic hyperplastic

changes and malignancy in the breast, the authors are able to provide pathological and clinical evidence of similar changes which precede cancer of the rectum.

Multiple adenoma presents the best clinical example of the simple adenoma which undergoes malignant change and develops into typical carcinoma. The histological examination of large simple adenomata not infrequently reveals commencing malignancy.

If the portion of bowel removed at operation for excision of cancer is immediately examined after fixation, with a low power microscope, there will often be seen irregularities in the contour of the mucosa, not visible to the naked eye. These irregularities occur in multiple adenomatosis and early carcinoma and are seen to be due to a localized epithelial hyperplasia, which may be invisible to the naked eye and only detected by microscopic examination, or, on the other hand, may be large enough to be noticed as tiny, smooth, rounded elevations. These areas of hyperplasia represent the first stage of tumour formation, and in this connection there are three points of importance: (1) their frequent association with multiple adenomatosis and carcinoma, (2) their more frequent presence in the neighbourhood of a small malignant tumour than a large malignant ulcer, and (3) that they affect an area of bowel, several inches above and below the carcinoma. No sharp line of distinction can be drawn between this hyperplasia and adenoma. In practice the authors reserve the term adenoma for a glandular tumour visible to the naked eye and class as hyperplasia those areas only visible on magnification.

The sequence of events in the development of cancer may be divided into four stages: (1) localized patches of hyperplasia, (2) the appearance of a crop of sessile adenomata, (3) carcinomatous development, either in one of these pre-existing adenomata or in the neighbouring epithelium, and (4) the progressive enlargement and dissemination of the malignant tumour.

The precancerous state in the rectum is distinguished by irregular patches of hyperplasia and adenomatosis. Not every area of hyperplasia evolves into an adenoma, or the adenoma into cancer, for the hyperplasia may disappear and the adenoma may become pedunculated and be shed, or the onward march may otherwise be arrested. The authors cite several cases in confirmation of their findings. The truth seems to be that adenomata, once removed, do not occur in the same spot, but other adenomata tend to develop in the neighbouring mucous membrane. These arise as the result of the occurrence of progressive hyperplastic change over a fairly extensive area of the bowel epithelium.

It is very important that repeated sigmoido-

scopic examinations should be made in patients who have had adenomata removed, to determine the presence or absence of a fresh development of tumour

R V B SHIER

PATHOLOGY

Syphilitic Lesions as met with at Post-Mortem Examinations Cleland, J B, *Med J Australia*, 1928, xiii, 399

This paper gives the frequency of various syphilitic lesions as discovered in 1,600 autopsies conducted at the Adelaide Hospital from the beginning of 1920 to the end of 1927, and in 145 autopsies at the Mental Hospital

It was found that rather more than 4 per cent of the bodies of patients examined at the Adelaide Hospital showed syphilitic lesions. At the Mental Hospital less than 10 per cent manifested syphilitic infection.

Among the cases at the Adelaide Hospital syphilitic aortitis was by far the commonest lesion. In about half of the cases in which this occurred an aneurysm had resulted. In a considerable number of the remainder the disease affected also the aortic valve. In four cases it was thought that fibrosis in the lungs might have been contributed to by a syphilitic infection. There were three possible gummata of the lung, and one possible syphilitic pneumonia.

A. G. NICHOLLS

Obituaries

Dr Hamilton Allen, a graduate of McGill University (Med '72) died in March at San Diego, Cal., where he had resided for some years. He was a native of the vicinity of Kemptville, Ont., and attended the high school of that place before proceeding to McGill. Burial was made at Tacoma, Wash.

Dr James Rorison McLean, who died in Toronto on April 1st at the age of 57 years, was one of the best known medical practitioners in Northern Ontario and practised for many years in Sault Ste Marie, where he was resident physician of the Algoma Steel Corporation. He was born in Arnprior, Ont., a son of the late Rev James McLean, and after having attended the public and high schools in that town, proceeded to Queen's University, Kingston, where he completed the course in Arts. After graduation from McGill in Medicine, he spent a year as house surgeon on the staffs of the Royal Victoria and Western Hospitals in Montreal and, in 1900, established himself in practice in Sault Ste Marie. Late in 1915, Dr McLean enlisted in the C A M C and became attached to the 119th Overseas Battalion as medical officer. When that unit was broken up, he went to France as a member of the staff of No 2 Canadian Stationary Hospital and other institutions, and after the armistice was attached to the Ontario Military Hospital at Orpington. In 1919 he returned to Sault Ste Marie and resumed practice. Dr McLean was stricken with a hæmorrhage of the brain while at work in the Plummer Memorial Hospital at Sault Ste Marie and died a week later. In 1922 he was married to Miss May McCauley, of Sault Ste Marie, and, in addition to his wife, is survived by three daughters and one son.

Dr James Reynolds, a graduate of Dalhousie in 1900, died June 7, 1928, at his home in Upper Stewiacke. He was of a very retiring disposition, a lover of nature, of fishing and hunting, and, having retired from active practice some fifteen years ago, he was not well known by the profession generally. He was, however, a man of very fine intellect and well posted in his work. But once in these later years did he emerge from his retirement, and that was on the occasion of the Halifax explosion when he gave valuable surgical services for forty eight continuous hours.

Dr H. A. Bonner. A remarkable old character died in the person of Dr Hector A. Bonner in Toronto on June 8th. Born in King, 1850, seventy eight years ago, Dr Bonner graduated at old Trinity in 1877, and practised in the village of Chesley up to 1896. At this time the wandering spirit seems to have broken loose, and he departed to the Yukon, 1897, as surgeon to the Royal Northwest Mounted Police. While in the Yukon it seems he was able to take up land grants which eventually became valuable, and which he sold on his retirement from the police. He retired to Toronto in 1900, and after twenty years away from the profession, resumed work in 1920, and was in practise up to the time of his death.

Dr D. A. Clark, Assistant Deputy Minister of Health, died in Ottawa on June 13th. A graduate of Victoria in 1890, and of Toronto in 1891, Dr Clark had practiced in Uxbridge and later in Toronto, where he was known as a practitioner of unusual merit. With the outbreak of the World's War he at once went into the medical corps of the Canadian army and rendered noteworthy service, both as an active front line worker and as an organizer.

Wounded at the second battle of Ypres, he was returned to Canada, in 1917, appointed Assistant Deputy Minister of Health in the federal services. In 1919, he had been actively at his work up to a few months ago, when failing health compelled a retirement. As major in the C A M C Dr Clark was well known throughout the expeditionary force as a courageous and efficient officer. While at Ottawa he was recognized as an official of a most exemplary type.

Dr Sophia G. Laws. The death occurred in Pasadena on May 25, 1928, of Dr Sophia G. Laws of Windsor, N.S. She received her M.D. from the Women's Medical College of Philadelphia in 1903. She registered in Nova Scotia in 1917. Having been on the staff of the Nova Scotia Sanatorium for several years she began to practise in her native town. Being compelled to seek a change of climate she established a small sanatorium and has been in active work for some five years in Pasadena.

Philip Doane McLarren, M.D. C.M., one of the best known and most promising of the younger men in the medical profession in Nova Scotia passed away

May 25, 1928, at the early age of thirty two years. He died at the Victoria General Hospital, Halifax, of pneumonia after but one week's illness.

Dr Philip McLarren was born in Halifax in 1896, the son of Prince Doune McLarren, for many years superintendent for Nova Scotia of the Canada Life Assurance Company. Even in his early college days he showed that unmistakable talent which presages success, and when he graduated from Dalhousie University in 1917 he had the distinction of being characterized by medical men of the city as one of the most brilliant students who ever passed through that institution of learning. During the final year of his studies he was attached to the Staff of the Victoria General Hospital as an interne.

Immediately following his graduation Dr McLarren joined the Canadian Expeditionary Force, and served his country until the conclusion of hostilities. He took a keen interest in the work of the Royal Air Force and, attached to this service, was at one time stationed at Croydon airdrome in England. On his return to Canada he became attached to the Air Board as medical examiner of pilots and personnel, and he was also medical examiner for the Halifax Aero Club. An active member of this latter organization, he took a great interest in its work, and gave generously of his time in furthering its development.

At an early stage in his professional career he identified himself with the Halifax Medical Society, as well as the Medical Society of Nova Scotia and the Canadian Medical Association, having made his membership in all three effective for this current year. Dr McLarren held a teaching position in Dalhousie University and was on the staff of the University Clinic. Just eight months ago he was appointed assistant physician to the Victoria General Hospital.

In the city press, the day following his death, Dr E V Hogan, President of the Victoria General Hospital Medical Board, expressed the following tribute to his memory:

"In the sudden death of Dr McLarren Halifax has lost one of the most promising junior members of the medical profession, and his colleagues, who knew him so well, are stunned with the announcement. He has been cut off in the flower of his youth, when a long and useful life was just beginning to dawn, when the citizens of Halifax, those who knew him, were learning to love and appreciate his learning, his skill, but above all his cheery presence at the sick bedside and his kindly word to brighten the sick one's burden. And it is the poor—God's suffering poor—who will miss him most of all. He fought the fight by day, and by night, and like the gallant soldier that he proved himself in the past war, he fought on and on,

and some may say that he lost the fight and went down to defeat, but we who knew him and loved him will say, "No"—for he won a victory, a victory that was crowned by a glorious death, a martyr to the high ideals of a profession, whose motto is "I Serve."

Dr McLarren's death will be a hard blow to the medical staff of the Victoria General Hospital, for we, the older members of the staff, were looking forward to the day of our retirement, and it was with every confidence that we were preparing to lay down our burden and thrust it on the willing shoulders of our younger confrères, knowing that men of the type of McLarren would carry on and put no blot on the reputation of those who in their turn laid down the burden of alleviating the suffering of the sick poor, and went to their long and last reward.

To the widow and fatherless child our staff offers its deepest sympathy in their irreparable loss, but in the days to come may their grief be somewhat assuaged by the knowledge that his memory will be ever dear to the medical staff of our hospital."

S L WALKER

Dr E Rochette, solo surviving male member of his line in Canada, and one of the oldest physicians in the Province of Quebec, died in Oka on June 18th, after an illness of only a few hours, in his 79th year. The family of the Counts de la Rochette de Roche gondo settled in Canada more than a century ago. Dr Rochette was the last male of the branch here. The head of the family is Count Henri de la Rochette, of Auvergne, France. Other living members of the line are Countess des Bois Hebert Gasto de Tilly, Miss Letitia Rochette, niece, Mrs G W Jolicoeur, wife of the Coroner of Quebec, and a grand daughter, Mrs Henri de B Taschereau, of Montreal.

Dr Rochette graduated from Laval in 1872.

Dr T H Taylor. One of the best known medical practitioners in Montreal West passed away recently, in the person of Dr T H Taylor, formerly superintendent of the Western Hospital. Dr Taylor's death occurred at the Western Hospital, after a short illness, in his forty-sixth year. A native of Cumberland Mills, Que., he was educated at the Quebec High School and McGill University. After graduating from the latter institution he joined the Western Hospital staff as an interne, later becoming superintendent. For the past fifteen years Dr Taylor had practised in Montreal West, residing at 73 Westminster Avenue. He was an Anglican and a member of the Masonic Order. He is survived by his widow and four children.

BRITISH EMPIRE

The first annual meeting of the College of Surgeons of Australasia took place at Canberra on March 31, 1928. The formation of the College has met with much opposition as may be gathered from editorial comment in the *Medical Journal of Australia* (April 21, 1928).

"There has been a considerable amount of criticism concerning the methods that have been adopted by the founders of the College of Surgeons. This criticism began as a whisper and culminated in a shout. No one appears to challenge the objects of the institution. It seems that exception is taken by some to the endeavour

to apply a hall mark to certain practitioners whose training and experience gave them a right to stand in the front rank of surgeons. It is held that if this hall mark is so distinct that the community at large cannot fail to distinguish it, the reputations and earning capacity of less well trained and less experienced practitioners must suffer. This argument is specious, for it is essentially in the interests of the community that save in emergency surgical intervention should take place under the most favourable conditions. The life and the safety of a patient should not be endangered because a medical practitioner has to make a living

There are many general practitioners who have trained themselves to become skilful and competent as operating surgeons, the reputation of these men is well known to the community in which they live. Their colleagues soon realize their claims and admit their ability. But there are others who pose as surgeons without such justification.

The fact that the College of Surgeons is a self appointed body is an empty proposition. The British Medical Association was founded by a single individual. The Royal College of Surgeons began as a guild of self elected craftsmen and afterwards obtained official recognition and statutory sanction. Again offence has been taken on account of the methods of selection of the Fellows. Mistakes may have been made, but those

who have examined the procedure dispassionately and disinterestedly, will admit that honest caution has been exercised in the selection. Lastly, it has been claimed that the whole of the medical profession or at least the whole of the Branches of the British Medical Association in Australasia should have been consulted in regard to the machinery of the College. Had this been done, the College would have been useless and its essential object would have been defeated. The College of Surgeons of Australasia is a fact, in spite of the opposition. If it exercises wisdom in the manner in which it conducts its business and carries out its functions, it will have a great future. A few minor mistakes and errors of judgment are of small moment. The thing that matters, is that it is fearless in the prosecution of its ideals."

GREAT BRITAIN

William Harvey

The Tercentenary Celebration

"The international celebration in London of the tercentenary of the publication of William Harvey's 'De Motu Cordis' opened on Monday. In the morning the delegates, who had come from all parts of the world at the invitation of the Royal College of Physicians of London, were received by the King at Buckingham Palace, and later in the day they formally presented addresses to the President of the College and listened to eulogies of the man who is regarded as the founder of modern medicine.

Sir John Rose Bradford, President of the College, presented to the King one hundred delegates representing twenty eight countries. In the course of an address he said that Harvey's demonstration that the same blood must flow unceasingly round and round the body, visiting its remotest parts, swept away the visionary speculations of his predecessors and paved the way for a scientific explanation of the purpose of the circulation of the blood. Thus it was that the publication of the 'De Motu Cordis' had been rightly acclaimed as the birth day of physiology and of scientific medicine. His Majesty, in identifying himself with the commemoration of Harvey's work, was but treading in the footsteps of his Royal ancestors. King James I. and King Charles I. both set a true value on Harvey and made him their own physician, and the latter supplied him with the bodies of deer from the Royal herds for his anatomical studies. Harvey constantly brought to King Charles natural curiosities for his inspection, and exhibited to him much of his experimental work. Together also they shared the rare experience of watching the beating heart in a human subject through a defect in the chest-wall produced by disease. In the Civil War, too, Harvey stood by his Royal master, and was present at Edgehill, in charge of the young Princes Charles and James, and afterwards at Oxford, where by Royal mandate Harvey was appointed Warden of Merton College.

The King, in reply, said in part—

'I thank you sincerely for your address. It is a great pleasure to me to join with my people in welcoming the many distinguished men from my Overseas Dominions, and indeed from all parts of the civilized world, now assembled in London in honour of the tercentenary of Harvey's immortal discovery.

'I appreciate the comparison drawn in your address between my part in to day's ceremony and the action of my predecessors, who befriended Harvey in his lifetime. I am proud to think that the Kings of England of that day, recognizing Harvey's great gifts, granted their patronage and help in his work, and are thus entitled to the credit of having contributed to the new birth of medical science.

'The importance and value of William Harvey's work cannot be exaggerated. In an age when physiological knowledge was in a state of darkness and chaos, he laid the essential foundation for a science of physiology by demonstrating not only the fact of the circulation of the blood but the manner in which it took place. He discerned and taught that the true method of scientific progress is by observation and experiment, and it is for this, and not merely as the author of a single discovery, however brilliant and fundamental, that we to day do honour to the name of Harvey.

'Science, as you truly say, knows no boundary of race or nation. Harvey's own career is an instance of this. He was a graduate not only of our own Cambridge but also of Padua, which ancient and illustrious University I am happy to see represented here to day. And we may proudly note that Harvey, in his three fold capacity as a successful physician in private practice, as physician to St Bartholomew's Hospital, and as an eminent student and investigator, foreshadowed what is now, and has long been, characteristic of British physiology—the combination of research with medical and surgical practice, allied with a generous devotion to the service of the poor in the public hospitals'—*The Weekly Times*, May 17, 1923.

A reception was held in the library of the Royal College of Physicians on May 14th, when the President, Sir John Rose Bradford, received the delegates and distinguished guests in connection with the Harvey Tercentenary. The occasion was made more noteworthy by the conferring of Honorary Fellowship of the College on the Earl of Balfour, Sir Ernest Rutherford, Professor Pavlov, and Professor Wenckebach.

Harvey's connection with St Bartholomew's Hospital was commemorated by a luncheon in the Great Hall on May 15th at which Sir Wilmot Herringham delivered an address on Harvey's work and life.

The celebrations concluded with a banquet given by the Royal College of Physicians at the Guildhall on May 16th, at which a very brilliant galaxy of guests was present.

Other features were the visit of some of the delegates to Harvey's old College of Merton, Oxford, and of others to Gonville and Caius College, Cambridge, where Harvey took his B.A. degree.

The Winnipeg Annual Meeting in 1930

During the past three weeks the Officers and officials of the British Medical Association have been in consultation, in regard to the details of the Winnipeg Annual Meeting, with two delegates specially sent by the Canadian Medical Association for this purpose. These delegates were Dr. T. C. Rontley, General Secretary of

the Canadian Medical Association, and Dr J D Adamson of Winnipeg, a prominent officer of the Manitoba Medical Association. The arrangements provisionally decided upon will be submitted to the Council at its June meeting, but members will be interested to know that the delegates showed that much thought had been already given to the arrangements in Canada, that every facility for interest and enjoyment will be given, not only at Winnipeg, but in every part of Canada which members can find time to visit, and that the Canadian Medical Association in general and its members in Manitoba in particular, would cordially welcome a large attendance. The representatives of the British Medical Association had the pleasure of entertaining Dr and Mrs Rontley and Dr and Mrs Adamson to lunch at the May Fair Hotel on April 25th. Dr and Mrs Rontley left for Canada at the end of the week but Dr Adamson is staying for several months to do some post graduate study, and will be a delegate of the

Canadian Medical Association at the Annual Meeting of the British Medical Association at Cardiff—*Brit M J*, May 5, 1928

A life of exceptional promise has been cut short by the death at Accra, West Africa, of Dr William Alexander Young, director of the Medical Research Institution of the Gold Coast. Young was closely identified with the yellow fever investigation of the Rockefeller Commission in West Africa, and appears to have succumbed himself to yellow fever while carrying on work on that disease. His death follows, within eight days, that of his colleague, Hideyo Noguchi. Another colleague, Dr Adrian Stokes, died last year from yellow fever. These three men have fallen in the active service of humanity.

Young was born in 1889 and was educated at Forfar Academy and University College, Dundee, (St Andrew's University).

GENERAL

The Twelfth Session of the Health Committee of the League of Nations

The twelfth session of the League Health Committee, held at Geneva from April 30th to May 5th inclusive, was attended by most of the overseas members of the Committee.

The members at present are

President Dr Th Madsen, Director of the State Serum Institute, Copenhagen

Presidents (ex officio) M O Volghe, Secretary General of the Ministry of the Interior and of Health, Brussels, *President of the Comité permanent de l'Office international d'Hygiène publique*, Dr G Araoz Alfaro, *President of the National Health Department*, Buenos Ayres, and Dr H Carrière, *Director of the Swiss Federal Public Health Service*, Berne

Members Professor Léon Bernard, *Professor of Tuberculosis at the Faculty of Medicine in Paris*, Technical Health Adviser at the Ministry of Health, Sir George Buchanan, *Senior Medical Officer, Ministry of Health, London*, Professor J Cantacuzène, *Professor of Bacteriology and Director of the Institute of Experimental Medicine, Bucharest*, Dr Carlos Chagas, *Director of the Oswaldo Cruz Institute, Rio de Janeiro*, Dr Witold Chodzko, *former Polish Minister of Health*, Director of the State School of Hygiene, Warsaw, Surgeon General H. S. Cumming, *Chief of the United States Public Health Service, Washington*, Dr J H L Cumpston, *Director General of the Commonwealth Department of Health, Melbourne, Australia*, Colonel J D Graham, *Public Health Commissioner with the Government of India*, Dr C Hamel, *President of the Reichsgesundheitsamt, Berlin*, Dr Alice Hamilton, *Harvard University*, Dr N M J Jitta, *President of the Public Health Council of the Netherlands*, Professor Ricardo Jorge, *Director General of Public Health, Lisbon*, Dr A. Lutrario, *former Director General of Public Health, Ministry of the Interior, Rome*, Dr Nagayo, *Head of the Institute of Infectious Diseases, Tokyo*, Professor B Nocht, *Rector of the University and Director of the Institute of Tropical Diseases, Hamburg*, Professor Donato Ottolenghi, *Professor of Hygiene at the Royal University of Bologna*, Professor Gustavo Pittaluga, *Professor of Parasitology in the Faculty of Medicine at Madrid*, Dr L Raynaud, *Inspector General of the Public Health Service of Algeria*, Dr M. Tsurumi, *Representative of the Public Health Service of Japan*, Dr C E A Winslow, *Professor of Hygiene at the Yale Faculty of Medicine*

A few of the salient features of the report of this meeting are here presented

In the matter of broadcasting information in regard to health conditions in the East, the Epidemiological Intelligence Bureau is now in weekly communication with 140 ports, and in this way all may be accurately posted as to the prevalence and distribution of infectious diseases. Reports have been received from this bureau indicating that yellow fever has reappeared in West Africa.

A program in regard to the interchange of medical health officers and sanitary engineers between different countries, for the purpose of discussing problems of civic and rural hygiene, was drawn up for 1928.

The Committee approved the report and recommendations of the Cancer Commission, including the formation of the expert sub-commissions for the study respectively of occupational cancer and certain aspects of the radiological treatment of cancer. It is known that certain callings (some methods of cotton spinning, the process of briquette-making, work in cobalt mines, one branch of aniline dye work, and work involving contact with tar) increase susceptibility to cancer, but there is a very irregular distribution of cancer in different countries even in the same industries. Valuable lessons on the causation of cancer could be learned from the intensive study of the causes of this unequal distribution. The application of preventive methods also needs enquiry.

The great value of the radiological treatment of cancer has been demonstrated by experience, but there is a lack of agreement as to the precise action of the rays and the best methods of applying them. A study of the basic principles of the methods followed in a number of the most successful institutes in different countries would be of great practical value.

The Committee approved the suggestion of the Smallpox and Vaccination Commission that the enquiry into the incidence of smallpox in Europe should be continued and extended to North America and the Dutch East Indies. At the present moment there is very little smallpox in Europe, which makes it possible to study closely such cases as appear, in order to determine, for instance, the exact rôle played by vaccination in reducing sickness and deaths, and to study the value of measures to prevent any future increase of the disease. There is a good deal of mild smallpox in Great Britain and Wales, but the continent is almost free of the disease. The Commission is also studying a number of points concerning the preparation, use, and effect of different vaccines.

The Committee took note of a memorandum submitted by Dr Jitta on the possible dangers resulting

from the increasingly widespread use of x rays, and requested the Medical Director to ascertain the existing laws or regulations on this subject in different countries and any other information bearing on action that has been or should be taken to obviate such dangers.

The Health Committee noted that the enquiry into infant mortality in Austria was concluded last December, and that in Great Britain in January, and the enquiries in the other European countries were still under way. The preliminary enquiries in Latin America are concluded, and the enquiry, properly so called, is being carried out in certain districts in Brazil, Uruguay, the Argentine Republic and Chile for a period of twelve months.

As in previous years special courses on malaria, followed by a stage of practical work in malarial countries, have been arranged, and are this year to be held in London, Hamburg, Paris and Rome. Fourteen scholarships are awarded for these courses by the Health Organization, in addition to those provided by the International Health Division of the Rockefeller Foundation.

The Council of the League of Nations recently adopted a resolution concerning the recommendation of the International Opium Convention, to which Canada is a signatory, to the effect that Eucodal and Dicode are narcotics capable of producing harmful results similar to those specified in the Convention, and should subsequently be subject to its provisions. They, therefore, recommended to the states signatory to the International Opium Convention that action be taken in regard thereto. As a result, the Government of the Dominions of Canada has passed an Order in Council, which comes into effect on June 12th, adding these to the schedule of the Opium and Narcotic Drug Act.

An Order in Council has also been passed cancelling the last paragraph of Section 2 of the Regulations issued under the Opium and Narcotic Drug Act reading:

"All licenses issued under this Act are subject to cancellation in the event of a licensee being found guilty of an offence against any of the provisions of the said Act."

substituting the following therefore:

"Licenses issued under this Act are subject to cancellation at the discretion of the Minister."

International Conference on Cancer

An International Conference on Cancer, convened by the British Empire Cancer Campaign, will be held from July 16th to 20th in London, at the house of the Royal Society of Medicine. Physicians, surgeons, pathologists, and radiologists from all parts of the world, whose work has been closely associated with inquiry into the causes and cure of cancer, will attend, and the Royal Society and all the principal universities, medical schools, and

scientific bodies of this country have appointed delegates. Sir John Bland Sutton, Bt, vice-chairman of the Grand Council of the Campaign, will preside, and Sir Richard Garton, chairman of the Finance Committee, is acting as honorary secretary of the Conference. On Wednesday, July 18th, H.R.H. the Duke of York, President of the Campaign, and the Duchess of York will receive the delegates and their wives at Lancaster House (London Museum), which has been lent by the trustees for this purpose.

A representative delegation of Canadian x ray men will be present at Stockholm for the Second International Convention on Radiography, including Dr Bauld, of Montreal, Dr A. Stanley Kirkland, of St John, Dr Hamish MacIntosh, of Vancouver, Dr Geo MacNeil, of London, Dr Geo Malcolmson, of Edmonton, Dr Patterson, of Ottawa, Dr A. H. Pirie, of Montreal, Dr C. W. Prowd, of Vancouver.

International Medical Post-Graduate Courses in Berlin

These are arranged, with the help of the medical faculty of the University, by the Lecturers' Association for Medical Continuation Courses and the Kaiserin Friedrich House. Part of the courses take place at any time, part, only in October, 1928.

I PERMANENT COURSES

1 Courses for 2 to 4 weeks

2 Courses, as guest assistants in clinics, hospitals, and laboratories, for 2 to 3 months or longer, for gentlemen desiring to do practical work under systematic supervision.

II COURSES DURING OCTOBER, 1928

1 A general course on "Survey of progress in the whole medical field," with special reference to pulmonary diseases, October 1 to 13, 1928.

2 A special course for nose, throat, and ear specialists, October 8 to 20, 1928.

3 A post graduate course on paediatrics, October 15 to 27, 1928.

4 A post graduate course on "New methods of diagnosis and therapy," with practical studies and exercises, in the wards and laboratories of the Friedrichshain City Hospital.

5 Single courses in all special fields of medical science, including practical work.

The courses are held in German, but numerous professors are able to lecture in the English, French and Spanish languages.

The Office assists in procuring suitable lodgings, gives information re cost of stay, and arranges visits to clinics and operations, etc.

The office quarters are in the Kaiserin Friedrich-Haus, Luisenplatz 2-4, Berlin, N W 6.

NOVA SCOTIA

A number of nurses recently graduated from the training school of the New Waterford General Hospital, with appropriate ceremonies.

Miss Strum, Superintendent of Nurses, Victoria General Hospital, Halifax, has been elected president of the Association of Graduate Nurses of Nova Scotia.

The new Hospital for Infectious Diseases, Halifax, is approaching completion, and it is expected that it will be opened towards the end of June.

It is announced that plans are nearly complete for a new hospital, with accommodation for one hundred patients, for the Halifax Infirmary. The Infirmary is conducted by the Sisters of Charity, and has had a highly creditable career in its present building on Barrington Street which goes back over many years. For the new building a much quieter site has been selected, on Queen Street, at the corner of Morris Street. The new hospital is to be of fireproof construction, and will embrace all the latest ideas in the way of convenience and equipment.

A dispute between the Sydney City Council and the City Hospital Board has held up the appropriation of funds for a new x ray plant for the hospital. It seems that the Hospital Board favour the appointment, as roentgenologist, of a physician who has had much experience at x ray work. The City Council, on the other hand, wish the position to go to a nurse who has had training in x ray technique. Neither side seems willing to yield, but the mayor has threatened the Hospital Board that if the appointment made by the Board is not cancelled, the hospital will not get its new x ray equipment. The hospital is owned by the City of Sydney.

Much regret has been expressed in Halifax at the removal of Staff Captain Clarke from the Grace Maternity Hospital (conducted by the Salvation Army). Staff Captain Clarke has been associated with Grace Hospital since its opening, and has shown much tact and wisdom in the direction of the institution during the trying times of the years of establishment. She has won the confidence and esteem of the people of Halifax. Before leaving Halifax, to take charge of the new maternity hospital at Ottawa, Staff Captain Clarke was made the recipient of a very substantial present from the ladies' auxiliary of Grace Hospital.

In the early morning hours of May 25th, fire was discovered in the Highland View Hospital, Amherst, which had already reached such proportions that, before the fire department could respond to the summons, it had spread practically throughout the building. Heroic work on the part of nurses and other members of the resident staff was rewarded by the safe removal of all the patients. Two of the nurses had a very narrow escape. The hospital was delightfully situated on high ground at a considerable distance from the centre of the town, and unfortunately, the firemen found themselves without a supply of water sufficient to cope with the flames. In consequence, within a few hours nothing but the brick exterior walls remained standing. It is understood that the insurance carried was \$100,000.00. Those in residence in the building lost all their effects, and several of the Amherst doctors lost instruments, etc. Dr A. E. MacKintosh lost his entire operating outfit, including a portable table which he had left in the hospital over night. The directors of the hospital decided at once to take over two large residences for temporary use. The Victoria General Hospital, Halifax, immediately expressed a complete operating room equipment, and the General Public Hospital, Saint John, offered such assistance as it could give. Within a very short time the hospital was carrying on in its temporary quarters, and one of the first to undergo a surgical operation was a veteran physician of Amherst, Dr C. W. Bliss.

Mr Evan Parry, consulting architect to the Federal Department of Health, spent some days in Amherst in conference with the hospital authorities relative to a new building, and Dr M. T. McEachern announced that the American College of Surgeons would be glad to assist by submitting plans, and otherwise. A new building will be constructed, but the matter of site has not yet been determined.

Dr J. P. McGrath, Kentville, has returned home after spending eight months in graduate study in the British Isles and on the continent.

Dr F. R. Little, Halifax, declined to accept nomination for reelection to the presidency of the Halifax County Conservative Association at its recent annual meeting, but was elected honorary president of the organization.

In order to meet a technical requirement of a state board of medical licensure, Dr S. J. Turel, who gradu-

ated from Dalhousie in 1917, returned to his Alma Mater this year for re-examination in the subjects of the final year in Medicine, and passed with distinction in every subject.

While in Montreal studying recent developments in medicine, Dr W. T. Purdy, of Amherst, was suddenly stricken with appendicitis. He was obliged to enter hospital at once, and was promptly operated upon. While for some days his condition was critical, it is learned that he is now progressing nicely and will soon be able to return home.

Dr W. D. Forrest has been re-elected chairman of the City Health Board, Halifax.

The May Examinations of the Provincial Medical Board resulted in the addition of twenty three names to the Medical Register of Nova Scotia.

At a meeting of the Provincial Medical Board, held on May 11th, only routine business was conducted. Nearly all the newly appointed members were present. Dr H. K. MacDonald, and Dr G. H. Murphy, Halifax, and O. B. Keddy, Windsor, were appointed to fill vacancies on the executive committee, caused by the retirement of Drs MacAulay, Hogan, and Sponagle.

The annual meeting of the Western Counties Branch of the Medical Society of Nova Scotia was held at Yarmouth on May 29th under the presidency of Dr G. W. T. Farish. After a paper by Dr A. E. Campbell had been read and discussed, Dr Elliott P. Joslin, of Boston, delivered an exhaustive and informing address on "The treatment of diabetes." This was followed by an animated discussion in which a large number took part, and which carried on to so late an hour that it was decided to adjourn until June 11th, when routine business and the election of officers will be disposed of and attention given to a communication from the Medical Society of Nova Scotia.

The Halifax Branch of the Medical Society of Nova Scotia is making arrangements for the unveiling of a memorial in honour of the founders of the Medical Faculty of Dalhousie University. The special committee, having the matter in hand, are securing a bronze tablet inscribed as follows —

In Memory of the Founders of the
Faculty of Medicine of Dalhousie University
1867

W. J. Almon, M.D., President	E. D. Farrell, M.D.
A. P. Reid, M.D., Dean	A. H. Woodill, M.D.
A. G. Hattie, M.D.	J. D. Ross, M.D.
G. Lawson, Ph.D., LL.D.	T. B. Almon, M.D.

Rev. James Ross, Principal Ex Officio

"They Built Better Than They Knew"

Placed by the Halifax Branch of the Medical Society of Nova Scotia.

1928

The cost of this tablet is to be met from branch funds. The Committee further suggest the placing on the wall in the medical building of enlarged photographs of early important persons connected with the Medical School. It is intimated that in this item doctors outside the city of Halifax might be interested.

W. H. HATTIE

An exceedingly important meeting of the Executive of the Medical Society of Nova Scotia was held in the Board of Trade Council room, Halifax, June 1st, from 7 to 11 p.m., with representatives present from the Dalhousie Refresher Course Committee, the Halifax Branch Society, and the Committee on the Dalhousie 60th Anniversary celebration.

The first business endorsed the mail ballot of the executive postponing the annual meeting until the fall and combining it with the annual Refresher Course of the Medical College.

The General Secretary for the Society reported that out of a possible membership list of 385 the first drafts had brought 265 fees. It was noted that some 30 more would complete their membership most certainly before the annual meeting. (As a matter of fact, at the present writing the list numbers 275.) The membership aimed at was 300 and there is no doubt but that the Society will "go over the top."

The Secretary was instructed to convey to the Valley Medical Society the appreciation of their courtesy in giving place to the Halifax Society as hosts for the annual meeting. The necessary steps were taken to hold the annual meeting during the week beginning October 15th, in conjunction with the annual Refresher Course of the Medical College and its 60th anniversary. The Society meeting being the 75th annual meeting, plans were approved to have fraternal greetings presented from all the other provincial associations present at this the Canadian Medical Association will co operate in furnishing speakers.

In case any visitors may think our hotel accommodation is not sufficient, it may be noted that the new Lord Nelson Hotel will be open to the public that week. The Society will therefore share in the opening festivities, the hotel being the official headquarters. All other Provincial Associations will be invited to send representatives to assist in the anniversary proceedings and the Refresher Lectures. A number of matters of general concern were laid on the table till after the Canadian Medical Association meeting in Charlottetown, as they would be dealt with then by the general body.

The announcement of the arrangements for the primary examinations in Canada for the Royal College of Surgeons was noted with approval, and publicity ordered to be given through the *Bulletin*. The establishment of Fellows of the College of Physicians of Canada was regarded as likely to do much to elevate the standing of the profession, and it was resolved that full publicity be given this matter also in the *Bulletin*.

The Executive considered that the proposed legislation introduced into the Canadian Senate, making venereal disease an impediment to marriage, was very desirable but the proposal was too drastic for adoption at the present time. The necessary instructions were issued to ensure the continuation of the publication in the lay press of weekly health articles that have been furnished for the past six months. These articles, as published under the auspices of the Society, were regarded as the best of their kind the press of Nova Scotia has ever had.

Full approval was expressed of the increased size of the *Bulletin*, and its mailing to every practitioner in the Maritime Provinces. It was felt that the amount of extra labour involved was but an expression of hearty sympathy with the Prince Edward Island men in their

undertaking the Canadian meeting, the additional cost to be adjusted with the Canadian Medical Association. The Executive extended fraternal greetings to the Medical Association of Newfoundland, which meets in annual session the week following the Prince Edward Island meeting.

A special Committee, consisting of the General Secretary, Dr G H Murphy, Dr Johnston of the Halifax Society, Dr Curry of the Dalhousie Refresher Course, and Dr McKenzie for the Dalhousie Anniversary, was appointed to do the necessary preliminary work in connection with arranging for the big medical week in October. It is safe to say this will be the big event in the history of medicine in Nova Scotia.

The annual meeting of the Pictou County Branch of the Medical Society of Nova Scotia was held in Pictou on Wednesday, June 13th, for general business. The scientific part of the program was carried out the latter part of March, when Drs Adamson and McKay, of Winnipeg, were the chief speakers, each giving two addresses. It may be noted that the first meeting of the Medical Society of Nova Scotia was also held in the town of Pictou. We are not sure, but it is quite probable that Pictou was selected as being the home town of Dr John Stewart who had then just recently come to Halifax.

The entire city of Halifax and the many friends of Dr G H Murphy were shocked to learn, the latter part of May, that his son, Arthur, a fourth year medical student at Dalhousie had been the victim of the "Hit and Run" motor car "skunk" driver. For several days his life hung in the balance. He had a severe scalp wound, three broken ribs, besides numerous bruises, and suffered severely from concussion. It was almost incredible to know that he managed to crawl home unaided almost half a mile. All will hope that the guilty person may be found and receive a lesson that will last him for life and be a warning to other such despicable characters.

The twenty four graduates of the Medical College this year are all settled for the present. It appears unfortunate that most of them are doing hospital service in the U.S.A., for the majority are then lost to Canada.

Dr Daniel McIntosh of Pugwash, an octogenarian over fifty years in practice, had his car turn turtle recently, but fortunately he escaped with a bruising and general shaking up. Yet, in a few days, he was back again looking after his practice in the community in which he sought refuge after a thrilling experience in a near by town some fifty years ago. He is an Honorary Member of the Medical Society of Nova Scotia, and is a regular attendant at medical meetings.

S L WALKER

NEW BRUNSWICK

In the Provincial Legislature recently an item for \$100,000.00 was put through the Finance Committee as an appropriation to provide a sprinkler system in the Provincial Hospital for the Insane at Saint John.

The public health legislation at the present session of the legislature in New Brunswick includes a recommendation to reduce the quarantine period for scarlet fever from six to five weeks.

The Board of Commissioners in the Saint John Public Hospital has authorized the purchase of another

radiographic unit in the X Ray Department, which will provide for two complete units operating in parallel, greatly increasing the efficiency of the department, which is coming more and more to serve the Province of New Brunswick as a whole.

The Federal Department of Indian Affairs has agreed to provide fifteen beds at the Saint John County Hospital for Indian patients, and also to pay the per capita cost for their maintenance. The department has also provided a nurse to look after the tuberculous Indians of Prince Edward Island and New Brunswick.

EPHEDRINE HYDROCHLORIDE "Frosst"

1— *The effects following the administration of Ephedrine are more prolonged than those of Epinephrine*

2— *Ephedrine, unlike Epinephrine, is absorbed from the alimentary tract without loss of pharmacological activity*

The field, previously restricted by the fleeting action of Epinephrine and the fact that the drug has always to be injected and therefore requires administration by a physician or nurse, has been very considerably widened by the introduction of Ephedrine. In the short time that it has been used, this drug has proved itself one of our most valuable therapeutic agents.

Ephedrine Hydrochloride "Frosst" is offered in the following forms —

TABLETS—MOULDED

For Oral or hypodermic use

No 277—Ephedrine Hydrochloride	¼ gr
No 278—Ephedrine Hydrochloride	⅜ gr
No 279—Ephedrine Hydrochloride	½ gr
No 280—Ephedrine Hydrochloride	¾ gr

SOLUTION

Ephedrine Hydrochloride 3% in distilled water 1 oz Bottles

Crystals ⅓ oz and ¼ oz vials. 1 oz Bottles

INHALANT—NASAL SPRAY

Ephedrine (Alkaloid) 1% in neutral oil, colored and pleasantly perfumed. 1 oz Bottles

— INDICATIONS —

Tablets

IN SURGICAL SHOCK—and in other cases of acute circulatory collapse, where the immediate increase of blood pressure is frequently a life saving measure, Ephedrine in doses of ½ to 2 grains, given by vein, hypodermically, or by mouth, will produce the desired rise in blood pressure, longer sustained than that effected by epinephrine.

IN HAY FEVER and ASTHMA—especially in the allergic and reflex groups, the daily administration, by mouth, of 1 to 5 grains in divided doses has afforded relief in a very large percentage of cases.

IN ASTHMA—due to infection, while the results are not so consistently good, the relief afforded to about 30% of these cases justifies its trial.

IN SPINAL ANÆSTHESIA—the fall in blood pressure may be anticipated and prevented by the administration, by mouth or hypodermically, of 1 to 2 grains of Ephedrine Hydrochloride just previous to induction of anæsthesia.

Solution

LOCAL APPLICATION—of Solution of Ephedrine results in the shrinkage of inflamed and congested mucous membranes. Its action here is more prolonged than that afforded by Epinephrine, and, in addition, the after irritating effects are usually absent.

NOTE—Solutions of Ephedrine Hydrochloride may be sterilized by boiling.

Inhalant

In Asthma and Hay Fever

Manufacturing Pharmacists Since 1899

Hospital Day was the occasion for broadcasting a talk on hospital affairs through Station CFBO, at Saint John, by Mr Ralph H. Gale, Superintendent of the General Public Hospital. The replies following this broadcasting intimated that it had been well received.

Dr A. A. Rowan, recently of the Everglade Sanatorium, has been transferred to the St Anne de Bellevue, D.S.C.R. Hospital, where he will handle the tuberculous branch.

Dr G. G. Melvin and Dr Wm Warwick recently spent several weeks as guests of the Rockefeller Foundation, visiting several Public Health Areas in the United States. It is felt that much benefit will accrue from this visit of the senior Health Officers in the Province.

During the last few weeks most of the hospitals in the province have held their graduation exercises and at most of them medical men have been asked to give

the addresses to the graduating class. Dr H. A. Farris was the speaker at Moncton at the Nurses' Graduation. Dr Stewart Skinner, of Saint John, was the speaker at the General Public Hospital and his speech was doubly interesting from the fact that for a long time he has been ill, but is now apparently well. His recovery gives great satisfaction to his friends.

Dr Stanley Bridges is at present in Boston doing intensive study in paediatrics. Dr Bridges intends to specialize in diseases of children on his return to Saint John.

Dr Vincent Doucet of Richibucto has been awarded the French Government Scholarship for 1928-29. He will continue his French Course in medicine at Paris.

Dr A. Stanley Kirkland will sail on June 15th for Europe for a two months' course of study. During this time he will attend the second international convention of radiography at Stockholm. A. STANLEY KIRKLAND

QUEBEC

The Hospice St Charles, badly damaged by fire on December 14th last, when thirty children lost their lives, will be repaired in the near future.

The St François d'Assise Hospital is to have an annex built in the near future, a building permit having been issued by the municipal department of the Public Works, at a cost amounting to \$135,000. The contract calls for the completion of the work by September next year. The annex will be used as a residence for the nuns who operate the hospital.

The activities of the Crippled Children's committee of the Rotary Club for the last year were detailed in the annual report. In view of the keenly felt need in Montreal for accommodation for convalescent crippled children, they felt justified in equipping a ward containing sixteen beds at the Refuge de la Merci, 361 St Paul Street, to be entirely devoted to this purpose. The budget showed that the entire \$950 appropriated for this cause had been spent, together with an additional \$300, contributed by members for special cases. The report read in part: "Seven hundred and fifty dollars were donated by Miss Tyndale to apply on the cost of food for the operation of the summer camp for crippled children at St Sulpice, Quebec, which was opened the first week in July, 1927, and operated for a period of eight weeks. The committee is convinced that the summer camp is a wonderful thing for the good of the crippled children on the Island of Montreal, and the committee would strongly recommend that future Rotarian Crippled Children's committees carry on in assisting the operation of the camp. During the year nineteen cases of crippled children were handled by the committee."

The second annual meeting of the Laurentian Sanatorium Association, which was held recently, revealed the fact that the total deficit is \$82,182. The President, Louis Colwell, pointed out that the deficiency for the year 1927, amounting to \$47,771, was caused by the maintenance of 160 beds for the indigent for whom the Association receives only \$1.34 per day, whereas the actual cost of maintenance is \$2.37. Mr Colwell said that it was possible that at an early date the institution would be compelled to make its first appeal to the public on behalf of the tuberculous, in order that the accumulated deficiency might be wiped out, and also to provide additional and much needed accommodation. He announced that in future it would be necessary for the Association to adhere strictly to the terms of its contract with the Provincial Government. "From the point of view of medical treatment of those suffering from tuberculosis, we feel that the association has every right to be proud of its record. The report of the resident medical superintendent will clearly demonstrate the curative value of our institution which has been visited during the last year by leading specialists from the United States, Great Britain, and France and all these have been unanimous in their praise of the treatment and care given to our patients." The average number of patients was 223. The average number of indigent patients was 54, showing that the average number of paying patients was 169. "It is impossible for the Association to carry on with a net loss of 93 cents per hospital day for indigent patients. While we are obliged to maintain 160 beds for public patients, which means that the maximum number of beds in use at any one time was greatly in excess of this." The Association must maintain 160 beds for indigent patients, but in no case can it afford to receive a greater maximum number than this. In that case, it may prove that the average number of public patients will be much less than received this year. Dr J. E. Byers, told the members of the Association that the sanatorium maintained by them was the cleanest institution in which he had set foot. He commented also upon the happy home life of the patients while sojourning in the institution. Many of them were reluctant to return to the city when pronounced cured, for they had come to regard the sanatorium as their home.

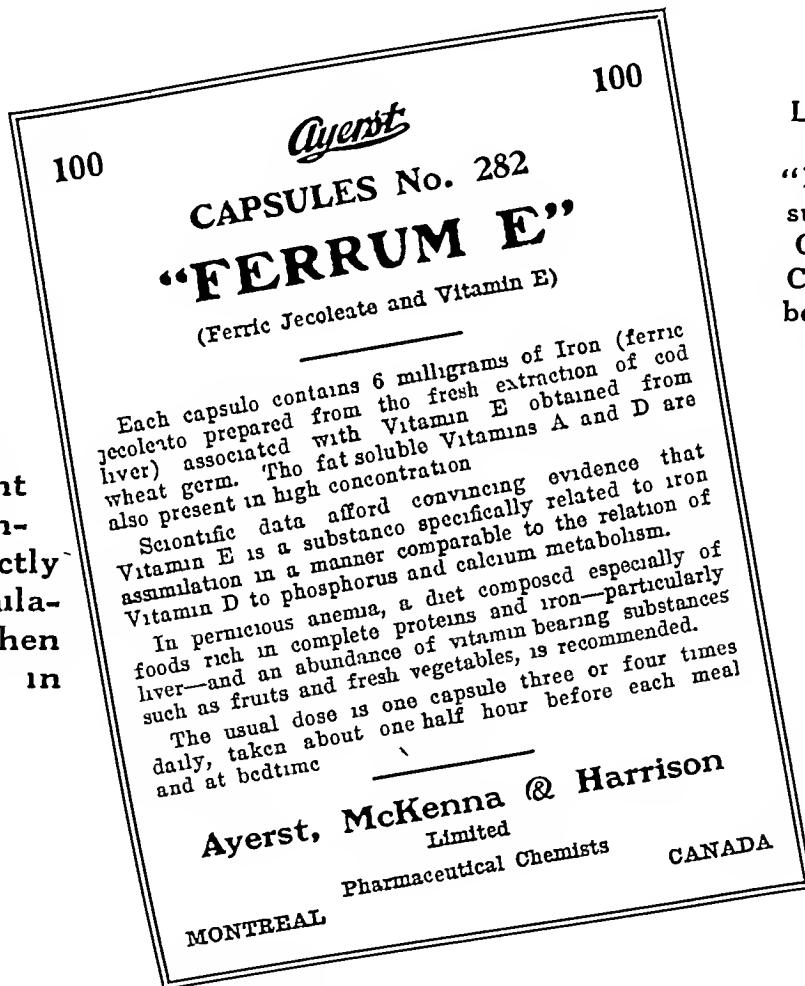

On April 1, 1925, the University of Montreal opened a health centre at 655 Demontigny Street east, the Montreal Anti-Tuberculosis and General Health League, the Metropolitan Life Insurance Company and the Provincial and Municipal Health Department contributed their financial support to the undertaking, which was placed under the medical supervision of Dr Baudouin and the management of Nurse Edith Belle Hurley. It was called the School of Public Health Nursing of the University of Montreal, and its definite aim was to cut the rate of infant mortality in the city. Nurse Hurley, with the co-operation of four visiting graduate nurses, assisted by 10 nursing students, has achieved splendid results. At first the school's effort was concentrated in the health work to be done in the parish of

NEW IRON THERAPY

"We believe that our data afford convincing evidence that in Vitamin E we have a substance specifically related to Iron Assimilation in a manner comparable to the relation of Vitamin D to Phosphorus and Calcium Metabolism."

—SIMMONDS, BECKER and McCOLLUM (Baltimore), (J.A.M.A., April 2, 1927).

Clinical tests with this product have shown excellent results and indicate a distinctly better assimilation of iron when administered in this medium.

Literature and Samples of "Ferrum E" as supplied at the Charlottetown Convention will be furnished on request

In prescription packages of 40 & 100 capsules

Ayerst Capsule No. 282—"Ferrum E"

Ayerst Capsule No. 283—"Ferrum E" with Arsenic (1/150 grain)

Ayerst Capsule No. 284—"Ferrum E" with Arsenic and Strychnine (1/80 grain)

Ste Catherine It was afterwards extended to take care of the needs of numerous families in the parish of the Sacred Heart Both parishes have a heavy population and it had been known to the authorities that their infant death rate was very high When Nurse Hurley and her colleagues took charge of the work the death rate among infants aggregated an average of 220 per 1,000 births As a result of a concentrated effort carried out scientifically, this rate of 220 per 1,000 has been reduced in less than five years to 86 per 1,000 This is said to be the most splendid achievement ever attained on the North American continent in so short a period As a direct consequence, and taking into account the heavy average of infant mortality in Ste Catherine's parish, the general toll of child death in this city, which was in 1923, of 148 per 1,000, has been reduced in 1926 to 119 The infant death rate from 1916 to 1925 in Montreal was of 1651 per 1,000 Miss Hurley's health centre is the only health organization in America doing preventive vaccination against tuberculosis Since June 26, 1926, more than 600 infants have been inoculated with Calmette vaccine The vaccine is administered in three inoculations, on the third, fifth, and seventh days after birth At the inception of her work, Miss Hurley found that most of infant deaths were due to bottle feeding, under unsanitary conditions She has steadily advocated maternal feeding, and when found impracticable or inadvisable, she has given simple and efficient directions to mothers on sanitary feeding Thus, through more sanitary feeding, and through immunizing infants against the scourge of tuberculosis by the Calmette vaccine, Nurse Hurley, seconded by a small staff of most capable and zealous assistants, has achieved results unknown in any other great city of North America.

A drop in both birth and mortality figures for the city of Quebec was shown in the statistics just issued by the Provincial Bureau of Health The first three months of the year, as compared with the same periods in the two preceding years, show a marked decrease in all

figures and more especially in infant mortality of under one year

In comparison, Montreal is shown to have a birth rate below the provincial average The marriage rate is above average and the death rate is just a shade below average The city of Quebec has fewer marriages, more births, and more deaths, in percentage

Dr A Grant Fleming, who has been Acting Director of the Department of Public Health and Preventive Medicine at McGill, during the past year, becomes the Director of that department

Dr Georges Prefontaine, professor at the University of Montreal, left Montreal recently to pursue special studies at Roscoff, in the Finisterre department, France, where the Faculty of Sciences of the University of Paris maintains a laboratory for deep sea zoological research Professor Gerard Gardner, of the same university, is leaving soon for Paris He will complete his post graduate studies in bacteriology at the "Institut Pasteur," under Professor Pettit

GEORGE HALL

Under the auspices of the Post Graduate Committee of the Province of Quebec Medical Association, a certain group of doctors of Montmagny organized a clinical day on May 22nd last, and invited, as well as the members of the profession of the county of Montmagny, their colleagues of the counties of Bellechasse and l'Islet. The great majority of the members of the profession answered the call, and considering the pitiable condition of the roads (it had rained for three consecutive days) the attendance was a marked success

Immediately following the meeting, a new Medical Society was formed comprising the physicians of the three above mentioned counties The officers elected were Dr Richard, of Montmagny, President, Dr Dion, of l'Islet, Vice President, and Dr Paradis, of Saint Gervais, Secretary

LÉON GÉRIN LAJOIE,

ONTARIO

The class of "Toronto 1896" was entertained at Brantford, on June 6th, by the members of the class resident in that city—Drs Marquis, Bier, Hicks and Nicol An unusually good representation of the class arrived to take advantage of the hospitality arranged for by the Brantford brotherhood. A buffet lunch at the Brantford Golf Club, afternoon golf, a sight seeing tour in Brantford, and a dinner in the evening made up a very full program. Members of the class from New York, Owen Sound, Goderich, Niagara Falls, Toronto and places nearby, constituted a gathering of seventeen at lunch, and twenty at dinner The class reports and business details connected with the re-union were presented by Dr W E Silcox, of Hamilton, to whose

energy and persistence the success of the reunions in the past is largely due At the dinner in the evening the details of the lives and activities of the absent and deceased members were presented, and each present was called upon to inform the class of his present behaviour and condition. The thanks of the class were expressed to the Brantford physicians, whose initiative had made the gathering such an unqualified success N B GWYN

The infant death rate in Toronto in 1910 was 158.5, in 1927 was 58.8 The death rate from tuberculosis in 1910 was 130.0, in 1927 was 61.6 The death rate from typhoid fever in 1910 was 44.2, in 1927 was 1.1 The general death rate in 1910 was 15.1, in 1927 was 11.0

MANITOBA

On May 16th their Excellencies, Lord and Lady Willingdon, and the vice regal staff, accompanied by the Lieutenant Governor of Manitoba, Hon Dr E W Montgomery, Minister of Health, Hon D L McLeod, Municipal Commissioner, Mr John McEachern, Chairman of the Manitoba Sanatorium Board, and other distinguished Winnipeg citizens, travelled by special train to Nette for an inspection of the Sanatorium Dr D A Stewart, superintendent of the institution, received the visitors and conducted them through the various

buildings At Lady Willingdon's request, the scholars in the sanatorium school were granted a half holiday Their Excellencies were greatly interested in the x-ray and examination rooms and also the arrangements for heliotherapy

The annual meeting of the Winnipeg Medical Society was held in the Medical College on May 18th Dr Oliver S Waugh, the retiring President, read an address on "The future of medical practice" The election of

FIRST!

Mead Johnson and Company studied samples of cod liver oil coming from the site of production, i.e., Labrador, Newfoundland, Nova Scotia, Iceland, Maine, Massachusetts, Japan, British Columbia and Norway, and found that Newfoundland oils were the most potent

Pediatricists noticed a difference in Cod Liver Oil and asked Mead Johnson and Company to make an investigation as to the origin of various cod liver oils

Mead Johnson and Company were

FIRST to place on the market a biologically assayed and standardized cod liver oil

FIRST to own and operate their own factories and rendering stations, thus controlling the oil from the time the fish were caught until it was placed in the bottles for the market

FIRST to place the oil in brown bottles, thus preventing the destructive effects of light

FIRST to use a proper seal to prevent the entrance of air causing oxidation of the oil

FIRST to arrive at standard laboratory methods for testing the oil for Vitamin A and Vitamin D

FIRST and only to test the oil from the livers of each catch of fish in preference to blending a number of batches of oil before testing. In this way batches of oils that do not come up to standard are rejected

FINALLY, Mead Johnson and Company place upon the market, oil of known origin and unquestionable potency

THE CANADIAN MEDICAL ASSOCIATION JOURNAL

officers resulted as follows President, Dr A T Vithers, Vice President, Dr Lennox Arthur, Secretary, Dr Wm Creighton, Treasurer, Dr M R MacCharles, Trustee, Dr S Campbell

A contract for the construction of St Anthony's Hospital and a power house, to be erected at The Pas, has been awarded to J Albert Tremblay, of Winnipeg. The hospital will be a four storey fireproof building and will contain room for 125 patients. The operating rooms will be complete and up to date in every detail. The completed building will cost \$250,000, and will be opened next January.

The annual meeting of the Manitoba Medical Society will be held in Winnipeg on September 10th and 11th.

Miss Cowan, daughter of the late Dr William Cowan, a veteran Hudson's Bay Company surgeon, has presented to the Medical Library of Manitoba University some interesting old books formerly owned by her father.

Dr C R Rice has been appointed Attending Surgeon to Grace Hospital, Winnipeg.

Dr Gordon S Fahrm of Winnipeg presided at the annual meeting of the American Association for the Study of Goitre at Denver, on June 18th, 19th and 20th.

John Stanley Hough, K C, president of the Winnipeg General Hospital Board of Trustees since 1921, died on June 7th, at the age of 72. His passing is greatly regretted at the General Hospital, as for many years he had taken a keen personal interest in its welfare.

A large number of Manitoba doctors attended the meeting of the American Medical Association at Minneapolis.

Dr A W Allum has left Winnipeg to practice in Los Angeles. For many years Dr Allum was on the staff of Grace Hospital, and was also Lecturer in Obstetrics in the medical faculty.

SASKATCHEWAN

At the regular monthly meeting of the Regina and District Medical Society, held May 9th, following a dinner at the Kitchener Hotel, Regina, Dr W A Dakin of Regina gave an excellent paper on "Hydronephrosis, causative factors, diagnosis, and treatment." There was a good attendance, and the paper was much enjoyed, as shown by the discussion that followed. Dr Dakin illustrated his paper by slides which he had prepared from cases.

At the previous meeting, the matter of care and education of defective children, and those who are deaf, dumb, or feeble minded in any way, in Saskatchewan, had been discussed. Drs U Gareau, O E Rothwell, and Lillian Chase, were appointed a committee to report at the meeting held May 9th. They brought in the following resolution, which was passed—

"Whereas Chapter sixty of the Revised Statutes of Saskatchewan, and part four thereof, makes provision for detention and committal of defective children, and, whereas, the general opinion of authorities is that defective children are not suitably provided for when admitted to mental hospitals, and, whereas, the practice at present existing in this province is to provide for the care of defectives in the mental hospitals,—There be it resolved, in the opinion of this branch of the Saskatchewan Medical Association, that the time has now arrived that the Government of Saskatchewan should earnestly be petitioned by the Provincial Body to make immediate provision for a suitable home, in order that the best interests of these unfortunates may be attended to and our Act more efficiently administered."

P L STRATH,
Secretary

During the last week in May and the first week of June another post graduate tour was conducted in this province. The speakers at these meetings were Dr M R MacCharles and Dr H D Morse of Winnipeg.

At the annual meeting of the Vancouver Medical Association, held on April 24th, Dr Walter S Turnbull was elected President for 1928-29. Dr Turnbull has

BRITISH COLUMBIA

been an active member of the Association in minor offices for the past few years. Dr Theo H Lennie was elected Vice President, Dr Lennie is the popular Secre-

The meeting in Regina, on June 4th, commenced in the morning when Drs MacCharles and Morse held consultations. At 12:15 p.m. a luncheon was held in the General Hospital, followed by a clinical discussion of such cases as presented. In the evening at 6:15 p.m. a dinner at the Hotel Saskatchewan was followed by addresses by the distinguished visitors.

Dr Morse gave an illustrated address on "The management of prostatic obstruction," and Dr MacCharles gave another on "A few experiences with malignant disease." They were exceptionally thorough treatises on the subjects, and were much appreciated by the local doctors of Regina and the district.

Dr MacCharles invited medical men of this district to co-operate with the Winnipeg and Manitoba men in making a real success of the visit of the British Medical Association to Winnipeg in 1930. Assurance of active support was given by men of the Regina and District Medical Society.

In Yorkton, there were eighteen doctors present at the meeting. Lectures were held in the afternoon, followed by a dinner, after which lantern lectures were given by the visiting team. This was an extremely successful meeting.

The Battleford District Medical Society had thirteen present at its meeting, which was held at the Mental Hospital, and a very hearty vote of thanks was moved to the visiting speakers for their splendid addresses. Meetings were also held at Moose Jaw, Saskatoon, Prince Albert, Swift Current, Weyburn, all were very successful and well attended.

The North Eastern District Medical Society held their annual meeting on May 28th, when the following officers were elected: President, Dr D R Livingstone, Melville; First Vice, Dr W E Somers, Foam Lake; Second Vice, Dr D Baldwin, Benito; Executive, Dr S M Rose, Yorkton; and Dr Findlay, Lemberg; Secretary, Treasurer, Dr A F Land, Yorkton; Representative to the Association, Dr A F Laird, Yorkton.

Weston's DIGESTIVE

A "whole meal" biscuit endorsed by doctors and dietists

Weston's DIGESTIVE is a real "health biscuit" made from the original old English recipe of the largest selling health biscuit in the world.

It contains, in delicious palatable form, mild laxative qualities especially suited to convalescents. Weston's DIGESTIVE is the only "fancy biscuit" many dyspeptics can eat.

George Weston Limited, Toronto
Makers of "Biscuits as they are made in England"

tary of the British Columbia Medical Association Dr G F Strong was again elected Secretary, and Dr J W Arbuckle will act as Treasurer

The question of closer co operation, or amalgamation, between the local and provincial Associations is a live topic in Vancouver and the province generally just now, and will be thoroughly discussed at the annual meeting of the British Columbia Medical Association next week. The Vancouver Association has already voted in favour of the proposed closer union

Dr F Epplen, of Seattle, addressed a meeting of the Victoria Medical Society on May 8th, giving an illustrated talk on "The diagnosis of kidney conditions." Dr M W Thomas, the President, was in the chair

The Victoria Medical Society held a luncheon on May 16th, at the Empress Hotel, when Dr Hermann M Robertson addressed the members, dealing in a most interesting manner with "William Harvey," this being the tercentenary of the revelation by the immortal Harvey of the circulation of the blood. Dr Robertson was warmly thanked by the society, on motion of Dr H E Ridewood, who spoke briefly of the value and interest in the series of lectures on Masters of Medicine inaugurated last month, when Dr Thomas McPherson delivered an address on "John Hunter," whose bi centenary was thus celebrated

Dr Hermann Robertson showed a copy of William Harvey's work in Latin and English, "*Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*," first published in 1628

The annual meeting of the No 6 District Medical Society, Vancouver Island, was held on May 7th, at Nanaimo, when an appreciative audience listened to lectures given by Dr G F Strong, of Vancouver, on "Blood pressure," and Dr Lyon H Appleby on "Intestinal obstruction" and "Strangulated hernia." Dr Wallace Wilson, President elect of the British Columbia Medical Association, also spoke on the activities of the provincial Association. Officers for the past year were re-elected. Dr A. D Morgan, Alberni, President, Dr W E J Ekins, Nanaimo, Vice President, and Dr O Ingham, Nanaimo, Secretary Treasurer

The annual meeting of the British Columbia Medical Association was held at the Empress Hotel, Victoria, on June 11th and 12th. A full report will be published in the next issue of the *Journal*

The Fraser Valley Medical Society reports that it has recommended to the Royal Columbian Hospital that it secure a basal metabolism machine. The annual meeting of the Society will be held in June

Much post graduate work is in store this year for the medical profession in this province. June 5th to 8th, Summer School at Vancouver, June 11th and 12th, at

Victoria, June 13th and 14th, at Kamloops, June 18th, at Fernie

The elaborate program of the Vancouver Summer School has already been published. At Victoria, Kamloops, and Fernie, clinical addresses will be given by Dr F A C Scrimger, V C, Dr F H MacKay, both of Montreal, and Dr Andrew Hunter, of Toronto. The meeting in Victoria will be held in conjunction with the annual meeting of the British Columbia Medical Association. A very complete program, scientific, business, and social, has been arranged. The entertainment part has been given special attention, and those who had the privilege of attending the Canadian Medical Association Convention in Victoria two years ago will know what this means. In July, Drs H B Cushing, of Montreal, and Dr A W Canfield, of Toronto, pediatricians, will visit the following places, giving lectures under the auspices of the Canadian Medical and British Columbia Medical Associations: July 3rd, Victoria, July 4th, Nanaimo, July 5th, New Westminster, July 6th, Chilliwack, July 7th, Vancouver

In August and September Dr A T Bazin and Dr A H Gordon, of Montreal, and Dr Gordon Bates, of Toronto will tour the province, giving lectures at the following places: Cranbrook, Grand Forks, Kelowna, Vancouver, Victoria, Nanaimo, Chilliwack, Prince Rupert and Prince George

The Summer School of the Vancouver Medical Association will be held the first week in June. Already the sale of tickets is highly satisfactory, and a good attendance is assured. This will be the eighth annual summer school to be promoted by the Vancouver Association

The new buildings which are being erected for the Vancouver General Hospital are making good progress and it is anticipated they will be ready for occupation about the New Year. The new buildings are a private ward pavilion and a maternity wing, which, together, will provide 240 beds

The graduating exercises of the training schools of the Vancouver General and St. Paul's Hospitals were held during the past month. Seventy nurses graduated from the Vancouver General and twenty eight from St. Paul's Hospital

Taking revenge for their defeat in Seattle on April 26th last, the Vancouver and Victoria medics met and turned back the Seattle invaders on the links of the Vancouver Golf and Country Club on May 10th, to the tune of 94½ to 67½ points

Dr G Morse of Port Haney has left for two or three months' post graduate work in the east. His practice during his absence is being cared for by Dr A. K. Connolly

Our deepest sympathy is extended to Dr A. S. Underhill of Kelowna, B C, on the death of his mother, Mrs. M J Underhill, of Vancouver, on May 13th

J EWART CAMPBELL

UNITED STATES

It is announced that Dr F D'Herelle, one of the world's leading bacteriologists, a Canadian, but for years a resident of Paris, will become professor of bacteriology at the Yale medical school. He is best known for his development on the subject of bacteriophage and has made important contributions in many fields of pure and applied bacteriology

Still retaining his Canadian citizenship, he went to

France to acquire his education. At the close of the war he went to Indo China and made a study of the relationship of bacteriophage to hemorrhagic septicæmia, including plague in man and in animals

Upon his return from Indo China, he spent some time at the Pasteur Institute and then went to the University of Leyden. At this university he received the degree of "M.D., *honoris causa*"

TETANUS ANTITOXIN

For the Prevention and Treatment of

TETANUS

Tetanus is an ever-present menace to all patients who present punctured or lacerated wounds, and modern medical practice calls for the use of a prophylactic dose of 1500 units of Tetanus Antitoxin in all such cases

The annals of the medical history of the Great War record not only the striking value of Tetanus Antitoxin as a preventive of Tetanus but also its notable value in treatment

Tetanus Antitoxin as prepared by the Connaught Laboratories is most carefully refined and concentrated and is particularly suitable either for intramuscular or for intravenous or intraspinal therapy.

Book Reviews

Gynaecology Howard A. Kelly, A.B., M.D., LL.D.,
and others 1043 pages, 767 illustrations D
Appleton & Co., New York, 1928

This is a remarkably good book. That it should be so is not surprising, when one remembers the content of Dr. Kelly's personal contributions to operative gynaecology and the contributions of his associates to gynaecological pathology. From a tremendous storehouse of drawings and pathological material a master has selected a series of original plates and drawings suited to depict all that is known of the anatomy, physiology and pathology of the female genitalia, then around these illustrations there has been woven a legend, primarily by Dr. Kelly himself, but also by numerous others, such as George Ward, Gellhorn, Burnham and Rubin, whose names carry authority in their special departments. Others, less well known, have been chosen by Dr. Kelly to write upon those subjects with which he personally knew them to be familiar.

"Anatomy" (Kelly), illustrated by the already well known drawings of Brodel, is followed by "Histology" (Glenn Craig) with numerous new illustrations, particularly of changes in the endometrium. A full description of gynaecological examinations and diagnostic aids, carries definite statements on the relative values of the different procedures. Special chapters deal with "Amenorrhoea," "Dysmenorrhoea," "Endocrinology and Organotherapy," "Congenital Malformation and Developmental Defects," "Sterility" (Wharton), "Periuterine Tubal Insufflation in Sterility" (Rubin), others treat of "Leucorrhoea," "Pruritus," and "Dyspareunia." Then follows, for the surgeon, perhaps the most interesting portion of the book, an extensive survey of operative procedures with sound advice on technique, pre-operative and post-operative care. This is naturally, for the most part, by Dr. Kelly, but the section dealing with pelvic floor plastics by George Gray Ward is so well written and well illustrated that one realizes, here particularly, the good judgment of the author in the choice of collaborators. The pathological section is interesting and complete, the chapter on endometriometria, by Lewis, being particularly timely. Protein therapy is dealt with by Gellhorn, radium by Burnham, and x-ray by Fricke, while Peterson has contributed a chapter on pneumoperitoneal roentgenology.

The above is a bare statement of some of the features of this remarkable book, which from its preface to its very end is full of words of wisdom. Indeed, after reading the preface, it is doubtful whether one would be willing to put it away, for, there, in a few words, the writer has compressed the history of gynaecology in America, has given honour to those who were his predecessors and contemporaries, and characteristically has pointed out the value of the contributions of younger men, so many of whom worked with his inspiration. A great clinician, a keen observer, and possibly the most expert operator in the field of gynaecology, has produced a book, which for that subject will take a place comparable to "Oler" in the field of medicine.

Pharmacotherapeutics Materia Medica and Drug Action Solo on Solis Cohen and Thomas Stokesbury Githens, Dr. Appleton & Co., 1928

As implied by the title, this book covers a wide field and not only is the undertaking ambitious but it

is carried out on an elaborate scale. The interesting historical note on the origin of "mithridatism" is an example of the detail. It has been attempted to produce something more than the ordinary pharmacological text book, by considering drugs from the point of view of the practitioner of medicine who finds that where the pharmacologist is able to be definite and exact regarding the action of drugs, he himself often experiences indefiniteness and not seldom contradiction. He finds, for instance, that there are drugs whose action on bacteria *in vitro*, or in animals, in no sense corresponds with their clinical value, witness the deadly effect of quinine on the pneumococcus, but its entire lack of specific action in pneumonia in man.

This is but one instance of how much clinical experience and laboratory experiments may diverge from each other. If they are to be reconciled a good step has been taken in the cause by bringing them together under one cover, according to the plan of this volume. In the main, drugs have been classified on a clinical basis, but due attention has always been paid to their chemical and pharmacological aspects. As regards the latter, it is a question whether there is not rather too much detail for the needs of the practitioner, but thoroughness is a good quality in which to be extreme.

The introductory chapters afford some interesting reading, although the style is not particularly easy. After an outline of the field to be covered, and some general definitions, a chapter is devoted to Disease and Recovery, with much laborious analysis. Chapter III is devoted to Indications and Contraindications, with many sound and useful hints. After this, the main theme of the book is begun in the chapter on "Drug Influence," with an exhaustive discussion of the many factors involved, physico-chemical, such as electrolytic dissociation, colloids and enzymes, hormones, the various forms of intra and extracellular influence, modification by function, general and selective actions, personal factors, such as idiosyncrasy, pathological factors, drug addiction, and sensitization.

A large amount of information with regard to the source and preparation of drugs is given, and a section is devoted to their therapeutic use, in which methods of administration are taken up in detail. There is a well balanced criticism of homeopathic doctrines under Schools of Medicine.

The classification of remedial agents has been made in accordance with (1) their uses in medicine (a) to combat the overtaxants of disease, (b) to alter tissue, (c) to modify function, (2) their dominant influences—which necessarily determine their chief use, (d) their predominant chemical components or proximate principles. As these determine in fluence and therefore use. As a minor point of criticism, it may be pointed out that the only mention given lipiodol is as a remedy for bronchomucositis whilst bismuth salts are referred to as those to be used for radiographic examination of the bronchial tree.

The work is well up to date, and judicious selections have been made of those therapeutic agents which are still on probation. Under Metabolic Adjuvants, for example, only the well known endocrine extracts are given place.

In general, the book is a thoroughly sound and comprehensive exposition of modern therapeutic methods, and will be useful to student and practitioner alike.

Clinical Examination of the Nervous System. G H Monrad Krohn, M.D., F.R.C.P. Fourth edition. 209 pages, 55 illustrations. Price 7/6. H K Lewis Co., 28 Gower Place, London W.C.1, England, 1928.

One may know at once that a manual of examination methods that reaches its fourth edition in seven years has not only found a place for itself but is being kept up to date. The first of these beliefs finds confirmation in the widespread use of the book by general practitioners, neurologists and teachers, the second, in the recent date of references in the book.

The object of the author has been to present a system of examination that, while not too long, will yet bring out all the significant details of functional disturbance that the case presents. One can only say that the object has been satisfactorily attained. The marks of long experience, both as clinician and teacher, are in evidence everywhere. A point that one especially notes with pleasure is a definite attempt to bring together the methods of neurology and psychiatry. The separation of these really inseparable subjects has been a detriment to both, and has been suffered much too long. Another point that will have an appeal is that the book is not a translation but is written in English by Professor Monrad Krohn himself. The disabilities of most translations are absent and the style is clear and emphatic. Only occasionally does one note expressions and constructions that are exotic.

The book is primarily intended for students, and much emphasis is placed on the inculcation, not only of an orderly and careful method of examination, but also of an orderly method of diagnosis based upon anatomical and physiological knowledge. The futility and uncertainty of trying to diagnose nervous disease by comparison of observations with text book lists of the characteristics of various clinical entities is emphasized, and will rouse an affirmative echo in the mind of those who practice and teach neurology.

There is no need to review in detail the author's presentation. One need only say that all the usual methods receive due notice, many of the less frequently used are mentioned, and throughout point and savour are added by interpolations from the author's own experience or from recent contributions to the literature. The illustrations are all good. Some of the diagrams are those most used in text books on neurology, but there are others of value that are new. The many half tone reproductions are remarkably clear and relevant.

The book covers different ground, but, in the present reviewer's opinion, is in the same class with Bings' *Compendium of Regional Diagnosis*, and that is saying a great deal. A T. MATHER.

Schizophrenia (Dementia Præcox) Edited by Charles L. Dana, Thomas K. Davis, Smith Ely Jelliffe, Henry Alsop Riley, Frederick Tilney, and Walter Timme. 491 pages and 61 illustrations. Price \$7.50. Paul B. Hoeber, Inc., New York, 1928.

This volume is number five of the series published by the Association for Research in Nervous and Mental Disease. It consists of the papers read at the meeting of the Association in New York in December, 1925. Most of the recent advances in this extremely interesting subject are discussed by thirty-one contributors, including the leading American authorities in psychiatry.

The twenty-six chapters are classified according to subject matter into nine sections as follows: Historical Survey and Delimitations, Statistics, Heredity and Constitution including Personality, Special Etiological Considerations, Investigative Aspects, Language and Art Productions, Pathology, Prognosis, and Treatment. The book is thus comprehensive in scope and treats of practically all phases of dementia præcox from its philosophical implications to its biochemical and endocrinological aspects.

This work shows that the knowledge of dementia præcox has increased considerably since Kraepelin first described it as a specific disease entity in 1898. There has also been a marked change in point of view since the Kraepelinian emphasis on course and outcome, with its rather pessimistic outlook. The present tendency is towards a greater emphasis on psycho-biological factors, both in symptomatology and in etiology. There is thus frequent use of such terms as maladjustment, disintegration, and to use Bleuler's expression, schizophrenia. In this connection, the discussion of the physical and mental personality types in schizophrenia and other psychoses will be found particularly interesting because of the light it throws on normal personality. Other contributions of special interest are those on language and art productions, autonomic and gastro-intestinal functions, and the relation of schizophrenia to other conditions such as alcoholism, acute infectious diseases, epidemic encephalitis, and the psychoneuroses.

A valuable feature of the book is the reproduction of the discussion which followed the presentation of each paper. Many otherwise obscure points and divergencies of view are thus brought to light. The book contains photographs of Kraepelin and Bleuler, the two psychiatrists who have contributed most to the understanding of dementia præcox. It also contains a number of very good bibliographies following special articles. It has an index of subjects and authors, and an appendix consisting of a list of members of the Association for Research in Nervous and Mental Disease. This book will be found both interesting and instructive to all physicians who wish to keep abreast of the times in their knowledge of schizophrenia and allied conditions.

J. W. BRIDGES

Principles and Practice of Obstetrics. Joseph B. DeLee, A.M., M.D., Professor of Obstetrics at the Northwestern University Medical School. 5th edition. 1140 pages, 1128 illustrations. Price \$12.00. London and Philadelphia, W. B. Saunders Co., Toronto, McAnish & Co., 1928.

The appearance of a new edition of DeLee's *Obstetrics* is an event of importance in obstetrical circles. Dr. DeLee is a stimulating writer and teacher and his book bears the impress of his personality. Whether one agrees unreservedly or not with all his conclusions, one has to acknowledge the great range of his experience, his ability as a teacher, his wide acquaintance with the literature of his subject and his desire to enhance the dignity of the art of obstetrics.

In this edition considerable space is devoted to prenatal care. Dr. DeLee remarks that there is no field in preventive medicine that offers the prospect of such glittering returns in saving human life and misery. He insists on the importance of pelvimetry, especially internal pelvimetry.

The chapters on the treatment of hyperemesis, eclampsia, abruptio placentæ, placenta prævia, rupture of the uterus, postpartum hæmorrhage, breech presentation and forceps operations have been almost completely rewritten. The modified Simpson forceps is preferred to axis traction forceps.

The low Cæsarean section, or laparotrachelotomy, an operation which offers many advantages, especially in possibly infected cases, over the classical section is well described and illustrated. The Gottschalk-Portes two stage Cæsarean section for preserving the uterus in frankly infected cases is described briefly.

The illustrations of injuries of the birth canal and the technique of perineorrhaphy and repair of the cervix bring out the surgical anatomy of the parts and are really helpful.

Although the book contains over eleven hundred pages it can be handled conveniently. The publishers,

Foot Troubles

Often Lead to Other Troubles

ONE of the most commonplace complaints of the average man and woman is seldom mentioned to the physician namely, the pain resulting from mere foot troubles

Improperly designed shoes produce symptoms such as fatigue—strains through the hips and back—nervous depression and kindred ailments. In such cases, quick relief is usually found in the

Cantilever Shoe

Men, Women and Children

The flexible shank exercises the foot muscles and stimulates circulation. Correctly shaped lasts encourage the foot to straighten out naturally. The snug arch of the Cantilever Shoe comes up to the hollow of the foot and gives it support without over-support, its shock absorbing faculties are in no way impaired. The heel is correctly placed, slightly wedged on the inner side to balance the weight properly.

Shoes for style, and shoes for service, made of the finest materials by skilled workmen, make the Cantilever a desirable shoe for all occasions.

Your local dealer will be pleased to demonstrate the men's and children's as well as the women's shoes.

HEAD OFFICE - - MONTREAL

W B Saunders Company, are to be congratulated on the excellence of the press work and the illustrations. This work can be heartily commended to the advanced student and practitioner
ROSS MITCHELL

Diagnosis of Disease Hobart Amory Hare, BSc, MD, LL.D. Ninth edition 528 pages, illustrated Price \$5.50 Lea & Febiger, Philadelphia, 1928

It is hardly possible to dwell too constantly on the importance of noting symptoms rather than of depending on artificial aids to diagnosis. In Martland Ramsay's words "There is too little study of what used to be called the face and mind of disease."

This idea has constantly guided Dr Hare in his excellent work, now in its ninth edition, and deservedly so. He has managed to compress a large amount of material into a small compass. If any one chapter were to be singled out for praise it might be that on the "Thorax and its viscera." In this he has discussed methods of examination and symptoms with directness and simplicity, and has employed illustrations that are unusually satisfactory.

H. E. MACDERMOT

The Extra-Ocular Muscles. A Clinical Study of Normal and Abnormal Ocular Motility Luther C. Peter, A.M., M.D., Sc.D. Professor of Diseases of the Eye in the Graduate School of the University of Pennsylvania. 294 pages, illustrated with 98 engravings and 5 coloured plates. Price \$4.00. Lea & Febiger, Philadelphia, 1927.

This work is based on lectures given by the author in the Graduate School of Medicine of the University of Pennsylvania. It is a sound, practical, and interesting clinical presentation of the subject of normal and abnormal ocular motility, and as such can be cordially recommended.

Our criticisms are that the text is marked by a looseness of expression which, though it does not seriously obscure the writer's meaning, does detract from the literary value of the book, and that, though the paper and printing are good, and the illustrations numerous and well chosen, the binding leaves something to be desired.

Practical Dietetics in Health and Disease Sanford Blum, A.B., M.S., M.D. Third edition 380 pages. Price \$4.00. F. A. Davis Co., Philadelphia, 1928.

The prescribing of dietaries makes frequent demand on the practitioner's time and thought. A book such as this therefore has a considerable place to fill. One of its first characteristics should be convenience of arrangement, and this has been striven for even at the expense of a good deal of repetition. The plan of taking certain cases briefly described and laying out diets for them is useful.

The directions regarding infant feeding are clear and easy to follow in the home. There is a rather noticeable lack of reference to the use of cod liver oil in the early months, and fruit juices are not introduced into the scheme of feeding until the sixth month.

The book has reached its third edition within five years and it is obvious that care has been taken to keep it well up to date.

H. E. MACDERMOT

The Art of Anæsthesia Paluel J. Flagg, M.D., Visiting Bronchoscopic Anæsthetist, Manhattan Eye and Ear Hospital. Fourth edition revised 384 pages, 135 illustrations. Price \$5.50. J. B. Lippincott Co., 201 Unity Bldg., Montreal, 1928.

Dr Flagg's book, the fourth edition of which has recently been issued, is nothing if not practical. In it are described not only those methods which are in daily use in large modern clinics, but also those that are practicable in private houses and in small hospitals where money to spend on equipment is strictly limited.

In the author's opinion ether retains its place as the most suitable anæsthetic for routine use. He has not much to say in favour of oil ether rectal anæsthesia, having found this method unreliable, and the preparations for it often distressing to the patient. An accurate estimation of its dangers, as he points out, cannot be made because the deaths from it have been allowed to go unreported.

The subjects of local and spinal anæsthesia might, with advantage, have been dealt with a little more fully. The chapters on "Carbon Dioxide and Re-breathing," and upon "Emergency Anæsthesia" are excellent.

Not all experienced anæsthetists will agree with the author's statements that there is no advantage in heating ether vapour, and that the preliminary dose of morphine and atropine should be omitted when the open method is to be used.

Those who are familiar with the literature published on the treatment of sudden arrest of the heart during anæsthesia will be surprised to find that nothing is said of the direct injection of adrenalin into the heart.

The reader unfamiliar with the American spelling and use of words will read this book with a feeling almost of bewilderment. For instance, "doze" and "yoke" are spelt respectively "doso" and "yolk." When we find "technique" spelt both "technique" and "technic" we find ourselves wondering whether "physique" and "physic" in the author's mind have the same meaning. It is a relief to find that Dr Flagg allows the word "anæsthesia" to retain its diphthong. When we read of a patient "who died spontaneously a few minutes before the anæsthetic was administered" we are forced to the conclusion that the anæsthetist was either unobservant or absent minded.

The illustrations are many and good, and the book full of useful hints to practitioners and students.

How about Cathartics?

*Modern science proposes a new
conception of the value of laxatives*

WHAT IS the efficacy of cathartics? Can we count upon purgatives to banish intestinal stasis and clear eliminative troubles away?

Physicians today are asking interestedly for more light upon these perplexing questions. The findings of modern science afford a positive answer. With one voice, students of the newer physiology say that cathartics do not promote intestinal health. Rather, they positively do harm.

Two famous students of physiological chemistry have written in an authoritative work on health:

"Physicians condemn regular or excess use of cathartics because they damage the alimentary tract. They tend to become ineffective unless the dose is increased, or the kind of drug varied."

ANOTHER authority, a surgeon known upon two continents, states that "a congested or abraded mucous membrane, such as exists in colitis, and such as results from the use of laxative mineral waters and other aperients and cathartics, cripples the defensive cells and opens wide the doors for the entrance of harmful bacteria and bacterial poisons."

There is a simple, natural way to deal with intestinal distress, amply supported by the highest authority. The preventives of constipation,

doctors tell their patients every day, are exercise, regular habits, and proper food.

For a *protective food* to promote intestinal health, doctors more and more recommend fresh yeast. Yeast really stimulates peristalsis, and tends to produce bulky stools of proper moisture content. Unlike cathartics, yeast is not habit-forming, and is non-irritating to the tender walls of the colon.

In cases of stomach disturbance and general debility, yeast produces a better appetite, marked leucocytosis, and increased metabolism. In furunculosis and other suppurative diseases of the skin the efficiency of yeast is too well known for comment.

PHYSICIANS usually suggest three cakes of fresh yeast daily, one before each meal or between meals. It may be eaten just plain, or dissolved in water, hot or cold—or any other way the patient prefers. For stubborn constipation it is most effective when dissolved in a glass of hot (not scalding) water, before each meal and at bedtime.

A copy of the latest brochure on yeast therapy containing a bibliography of articles and references on the subject will gladly be mailed on your request. The Fleischmann Company, Dept. 470, 208 Simcoe St., Toronto, Ont.

M

EAD'S Dextrin-Maltose, cow's milk and water, proportioned to suit the individual requirements of the infant, has given good results for many years

Nor has it been in the occasional case, but the *majority*, normal and difficult alike, that reflects the benefits of this carbohydrate (Dextrins and Maltose) combined with cow's milk and water to constitute the infant's diet

Infants on such a formula usually make satisfactory gains in weight. More, this weight represents sound musculature and not a mere "water logging" of the tissues such as especially occurs in highly sweetened mixtures

There is a minimum of nutritional disturbances from the use of Mead's Dextrin-Maltose, due to its larger absorption limits and ease of assimilation

It is invaluable to use with protein milk in cases recovering from attacks of fermentative diarrhoea, for it places the least tax upon the digestive tract of the infant

Mead Johnson & Co.
of Canada, Ltd
BELLEVILLE, ONTARIO

**MEAD'S
DEXTRI-MALTOSE**

"The different carbohydrates show different tendencies to fermentation. Milk sugar ferments most easily, less easily the cane sugar, and least the dextrin-maltose preparations"

"Infants will tolerate a much higher mixture of maltose and dextrin than either lactose or cane sugar"

"It is of great importance that this maltose and dextrin should be derived properly (not by the acid process, but in a natural way) by the action of the enzymes of sound barley malt upon cereal starch"

"Malt sugar (dextrin and maltose) seems to be more easily digested and better taken care of by infants having had much digestive trouble"

"Feeding the majority of Bottle Babies gives the advantages of the use of Mead's Dextrin-Maltose for infant feeding. Send in request with sufficient samples for trial purposes"

**Feeding the
Majority
of
Bottle Babies**

"Give Me the Gist of It!"

TODAY, when fresh advances are continually being recorded in every branch of medicine the busy practitioner demands—

"Boil it down—omit the non essentials Give me only the gist of current developments—authoritatively edited—in a form equally good for ready reference or rapid study—with emphasis on the practical rather than theory"

That is exactly what these complete in-one-volume Year Books do. They contain the salient points of hundreds of journals, American and European, selected and *personally commented on* by men of international standing.

This—and the fact that they are the lowest-priced standard works of their kind offered to the profession—is why they are used by more physicians and surgeons than subscribe to any Year Book. More of them are bought and used today than ever before in their 26 years of history. Today these books literally are

"Britesun" Specialist Carbon Arc Lamp

*An Efficient Portable Lamp for Localized
Ultra Violet Radiation*

A-70 Britesun
Specialist Carbon
Arc Lamp

THE Carbon Arc Lamp is "The nearest approach to natural sunlight," according to a statement made by the U S Bureau of Standards at Washington after a thorough investigation. Thus the Carbon Arc Lamp plays an important rôle in the field of light therapy.

Through the use of "Britesun" Specialist Carbon Arc Lamp it is possible to obtain a complete spectrum as in sunlight or to select any desired energy distribution within the spectrum by virtue of the nine different types of carbons available.

The "Britesun" Specialist Carbon Arc Lamp is designed for the Ear, Nose and Throat Specialist, or the General Practitioner for treatment of localized conditions such as skin diseases, carbuncles, neuritis, wounds and burns. The localizer is constructed for the use of all the standard Kromayer quartz applicators. This lamp is sold complete with localizing attachment, goggles and fifty Ultra Violet carbons and operates on 110 volts, either A C or D C.

HIGH BLOOD PRESSURE PATIENTS SUFFER MORE DURING HOT WEATHER

Hot, dry days induce rapid perspiration, increasing hemal viscosity, capillary stasis follows, then vascular congestion and so a vicious circle.

The nearer the primary cause in applying treatment the better will be the results. The degree of viscosity of the blood varies in the same individuals.

Blood pressure is high on dry days and low on damp days. During dry weather plenty of water should be drunk.

PULVOIDS NATRICO

(High Tension, Brunton Thrush)

is the product that thousands of physicians are using satisfactorily and successfully in the symptomatic treatment of High Blood Pressure, pending the determination of the cause and if possible its correction.

In Pulvoid form insuring prompt disintegration of friable aggregate and especially coated to traverse stomach intact and disintegrate in intestines, thus avoiding gastric disturbance.

1 to 3 Pulvoids q i d, or as directed by the physician.

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal-i-to-sis) N N L

(L Hahtus—Breath Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose, or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth, hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis

The volatile antiseptic constituents of Listerine—thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents, hence, Listerine is often corrective of these disorders associated with the endo development of gases and acid eructations. A large tablespoon of Listerine in a wine glass of hot water will afford immediate relief

A New EPHEDRINE NASAL SPRAY

for promoting

Sinus Ventilation and Drainage

EPHEDRINE INHALANT, Swan-Myers contains 1% solution of Ephedrine alkaloid in light mineral oil, colored for identification and fragrantly perfumed with oil of rose

It contains no aromatics, such as menthol, thymol, camphor or eucalyptus which frequently irritate and sting. Patients experience no discomfort from the cold air after the use of this spray. Applied as an oil spray, or as drops in the nose, this Inhalant will contract capillaries, reducing swelling of the turbinates and diminish hyperemia. It promotes sinus ventilation and drainage. Its action is prompt and sustained.

What ?

*Milk with a bacterial count
of less than 100 per c.c. ?*

Dryco is the milk of which this enviable record is true! The bacterial count is consistently below 100 per c.c. and these are harmless spore formers! This information is valuable to every physician who wishes to avoid the incidence of milk-borne infections which are especially prevalent among infants during the warm weather.

It is significant as to the merit of Dryco, that it has for years been prescribed by physicians all over the world. They know that it can be depended upon for good results and is of special value in difficult feeding cases. In addition to other points of superiority, Dryco is highly antirachitic, due to irradiation by the ultraviolet ray

PROPHYLACTIC POLLEN EXTRACTS

in a New Package

GROUP 1 GRASSES (Bio 360) GROUP 3 RAGWEEDS (Bio 364)
GROUP 2 CHENOPODS (Bio 362) GROUP 4 WORMWOODS (Bio 366)

THERE are five or more different pollens in each group, but the atmospherically prevailing pollen predominates—in group 1, timothy, in group 2, Russian thistle, in group 3, the common and giant ragweed, and in group 4, mugwort

Hitherto supplied in concentrated form, to be diluted for use, the grouped pollens are now available as glycerin extracts, so diluted as to contain in each cubic centimeter 20, 200, or 2000 pollen units, as labeled, each vial containing 4 cc. So without any trouble at all the dosage can be begun at 2 units (0.1 cc) and run up to 1600 units, or even 2000 if the practitioner so elects.

The glycerin extracts retain their activity throughout the season, and every package is dated. Complete course, \$9.00.

For Diagnosis The same groups are supplied for diagnosis in glycerin-boric acid paste form, in small collapsible tubes, singly (at 75c each) or in a package containing all four of the groups (at \$2.00). *Single pollen extracts* in tubes can also be had.

Complete directions for use are given in the circulars accompanying the packages and in our booklet on Pollen Extracts in Hay Fever.

HEXYLRESORCINOL SOLUTION S. T. 37

(Liquor Hexylresorcinolis, 1-1000)

A MAJOR ADVANCE IN THE FIELD OF GENERAL ANTISEPSIS

DESTROYS PATHOGENIC BACTERIA ON LESS THAN FIFTEEN SECONDS CONTACT, AND IS
NON TOXIC — NON IRRITATING — NON CORROSIVE
ODORLESS — COLORLESS — STAINLESS
ACTIVE IN THE PRESENCE OF ORGANIC MATTER

The remarkable bactericidal action of Solution S T 37 is due to the presence of HEXYLRESORCINOL, the most powerful non toxic antiseptic known. It has over SEVENTY TIMES THE GERMICIDAL POWER OF PHENOL, yet, as incorporated in this solution, it may be applied full strength in open wounds, or on denuded surfaces without injury or irritation. *HARMLESS if accidentally swallowed*

SOLUTION S T 37 has the low surface tension of 37 DYNES PER CENTIMETER, which increases the rate of diffusion of the germicide through the cell membrane of the organism, and materially enhances the germicidal action of the solution. Hence, the name, Solution S T 37

IMPORTANT to PHYSICIANS ESPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponde's Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician, but lacerations leucorrhoea gonorrhoea prolapse, post-operative and post confinement treatment, and uterine hemorrhage are some of the conditions in which Ponde's Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponde's Tampons.

Ponde's Tampons are packed in six tampons to a box and are made in the following medication:

A—Ichthyol Compound, Glycerin and Boro-Glyceride 50% Ichthyol 25% Resublimed Iodine 14% Carbolic Acid (absolute Phenol) 5%, Powdered Hydrastis 1% B—Ichthyol 10% Glycerin and Boro-Glyceride 50% C—Protargol and Ichthyol (Each 2%) Glycerin and Boro-Glyceride 50% D—Opium, Belladonna and Hyoscyamus Glycerin and Boro-Glyceride 50% Powdered Opium 2 grains Extract of Belladonna 1 grain Extract of Hyoscyamus 2 grains. E—Glycerol of Tannin 50% F—Ichthyol Compound with Silver Iodide Glycerin and Boro-Glyceride 50%, Ichthyol 25%, Iodine 14% Phenol 5% Powdered Hydrastis 1% Silver Iodide (made soluble by Potassium Iodide) 1% G—Glycerin and Boro-Glyceride, Glycerin and Boro-Glyceride 50% Resublimed Iodine 25% H—Plain Glycerin Gelatin base

Whenever Depletion is Paramount

As in—

Cervical or Inguinal Adenitis
Mammary Complications
Inflammation of the
Abdominal Viscera

Antiphlogistine is indicated.

APPLIED over the affected area, as hot as can be comfortably borne by the patient, Antiphlogistine, by virtue of its marked hygroscopic action, serves to deplete the enlarged glands, relieves the swelling and pain and adds materially to the comfort of the patient

This simple treatment, entirely compatible with internal medication, is becoming more and more an every-day procedure with uniformly gratifying results. The world-wide use of this topical application by the medical profession is the best evidence of its merits.

Some Facts about Carnation Milk

Unsweetened Evaporated

CARNATION MILK is unsweetened—
as distinguished from milk pre-
served by the addition of sugar

Carnation Milk is the whole milk and
nothing but the milk. Only part of the
water is removed from fresh, rich milk
from selected herds. Nothing is added.

Carnation Milk has a butter-fat content
never less than 7 1/2 per cent. It may be
easily diluted to any richness required
by adding pure water.

Carnation Milk is hermetically sealed
and sterilized—always pure and fresh.

Carnation Milk is easily digested by
infants, especially those who cannot
tolerate the protein of cow's milk in
other forms.

Carnation Milk is clean, pure, whole-
some, nourishing, convenient and
economical.

REG U S PAT OFF

Research ... the Result

THE first cleanable intensifying screen, the first grainless screen and the first double screen on the market were products of the Patterson Laboratories. The creation of these contributions to roentgenology was a formidable task. Its accomplishment is typical of the work of the Patterson Screen Co.

Today the problem is infinitely more intricate. Screens must be produced in quantity—yet each one must live up to the standards set by the perfect screens that it took years to produce. Each Patterson Intensifying Screen must have **SPEED—LACK OF GRAIN—FREEDOM FROM LAG—CLEANABILITY** and above all—**UNIFORMITY**. No one of these qualities may be sacrificed to obtain others.

Precise methods and painstaking care in manufacture—elaborate scientific tests that each screen must undergo before leaving the factory—assure consistent, satisfactory results to the radiographer whose cassettes are Patterson-equipped.

We shall be pleased to send a sample screen, free of cost, for the roentgenologist's own test.
